Emission standards to be applied to stationary sources of air pollution have also been characterized by change, confusion, and controversy. Most visible has been the debate about the efficacy and reliability of stack-gas scrubbers to remove sulfur dioxide from the effluent of coal-burning and oil-burning electric-power plants (see also Chapter 8). Electric utilities have argued that these devices are inordinately expensive and not reliable; the Environmental Protection Agency has insisted that scrubbers are a proven technology and should be applied. [24] The industry favors the use of tall stacks to disperse the effluent and "intermittent controls," meaning curtailment of operations or switching to low-sulfur fuels during adverse meteorological conditions. Emissions standards in force in 1976 for new fossil-fuelburning steam-electric-power plants are summarized in Table 104.

TABLE 10-3 Automobile Emission Standards (grams per mile)

	HC	*CO*	*NO_x*
Uncontrolled cars (pre- 1968) [a]	8.7	87.0	3.5

BOX 10-3 Air Quality Indoors

There are standards for air quality outdoors and in industrial workplaces, but most people spend most of their time in places where air quality is neither monitored nor regulated--in homes, offices, classrooms, stores, cars, buses, planes, and other enclosed places. Ironically, the concentrations of air pollutants in these heavily used indoor environments often exceed those that are permitted outdoors.

The few studies that have been done of air pollution in homes have identified several potentially important sources of harmful contaminants. Gas stoves, for example, emit nitrogen dioxide, nitric oxide, and carbon monoxide. In homes tested in a study for the Environmental Protection Agency, nitrogen dioxide concentrations often exceed 100 $\mu g/m^3$ in the kitchen and sometimes approached that concentration throughout the house; carbon monoxide concentrations sometimes approached 10,000 $\mu g/m^3$. [a] Presumably, improperly vented gas water heaters and furnaces can also contribute significantly to indoor concentrations of these combustion products.

Other indoor air contaminants are dispensed intentionally from aerosol cans of all varieties-deodorants, hair sprays, cleaning agents, and insecticides, among others. Of concern are not only the products themselves, but the fluorocarbon propellants found in many of them. Concentrations of the latter in some circumstances exceed the Threshold Limit Values applied in industry. [b]

The most pervasive form of air pollution indoors, however, almost certainly is tobacco smoke. The health risk that smokers impose upon themselves has been suspected for a long time and established beyond any reasonable doubt since the 1960s. The plight of some millions of American nonsmokers who are clinically allergic to tobacco smoke is well known to the victims and to the medical profession, but it has not been widely publicized. Also well established medically is the special threat that tobacco smoke represents for nonsmoking victims of asthma, bronchitis, emphysema, and heart disease. [c]

More recently, attention has turned belatedly to the possibility that tobacco smoke at concentrations commonly encountered indoors is hazardous to otherwise healthy, nonallergic nonsmokers. The risk to nonsmokers (more accurately, passive smokers, that is, people who inhale smoke *involuntarily* from their environment) should hardly come as a surprise in view of the large number of carcinogenic and otherwise toxic substances that have been identified in tobacco smoke. They include cadmium, oxides of nitrogen, benzo(a)pyrene and other hydrocarbons, carbon monoxide, and particulate matter. Probably many passive smokers have consoled themselves with the belief that the voluntary smokers sucking the smoldering tobacco are inhaling and absorbing most of the pollutants themselves. Unfortunately, studies have shown that the sidestream smoke--that which drifts off the tip of the cigarette--contains several times as much of the main pollutants as the mainstream smoke inhaled by the voluntary smoker. [d]

Obviously, the sidestream smoke is diluted by surrounding air before being inhaled by the passive smoker, but the dosage can still be substantial. Concentrations of particulate matter in excess of 3000 $\mu g/m^3$ have been measured in smoke-filled rooms at parties, or 40 times the U.S. standard for outside air. In public places, concentrations of particulate matter from tobacco smoke have been measured at up to 400 $\mu g/m^3$. [e] Carbon monoxide concentrations in smoke-filled rooms reach at least 40,000 $\mu g/m^3$ and prolonged smoking in enclosed automobiles has produced CO concentrations of 100,000

[c] See, for example, I. Schmeltz, D. Hoffmann, and E. L. Wynder , *The influence of tobacco smoke on indoor atmospheres*; and W. S. Aronow, *Effects of carbon monoxide on coronary heart disease*.

[d] On this and subsequent points, an especially good review article is Jon Tinker, "Should public smoking be banned?"

[e] In addition to Tinker, see W. C. Hinds and M. W. First, "Concentrations of nicotine and tobacco smoke in public places".

$\mu g/m^3$. Studies of the carboxyhemoglobin content in the blood of voluntary and passive smokers indicate that the passive smoker in unusually smoky conditions receives the equivalent of smoking one to two cigarettes per hour, and under conditions common in homes, offices, bars, and theaters receives the equivalent of smoking a cigarette a day.

Demonstrating conclusively that these kinds of exposures actually can cause disease (as distinguished from aggravating preexisting disease or allergy) among nonsmokers is difficult for many of the reasons enumerated in Box 10-2: A large population of subjects must be kept track of over an extended period if a statistically significant effect is to be discerned, many other kinds of insults will be operating in the same population at the same time, some of the other insults may interact synergistically with passive smoking, and so on. The most informative studies of which we are aware investigated the incidence of bronchitis, pneumonia, and other respiratory ailments among young children whose parents were heavy smokers; the children had a

significantly higher incidence of the ailments than the children of nonsmoking parents. [f] It is conceivable, of course, that the same part of the genetic makeup of certain persons predisposes them to respiratory ailments and also predisposes them to take up smoking; if this were true, there would be a correlation between smoking and respiratory disease in the smokers and their children, but it could not be said that the smoking "caused" the disease. Most authorities consider this hypothesis of a common genetic origin of smoking and respiratory disease to be inconsistent with the medical evidence. [g]

Whether there is a threshold in level of exposure to cigarette smoke, below which no lasting harm occurs, is not known and would be very difficult to establish. The appropriately cautious approach taken by most regulatory authorities in dealing with other insults, such as radiation, has been to assume for purposes of analysis that no threshold exists. If, on this assumption, the data for lung-cancer risk versus exposure to tobacco smoke among active smokers is extrapolated into the range of exposure suffered by passive smokers, the conclusion is that passive smokers exposed to the equivalent of one to two cigarettes per day may suffer a doubled risk of dying of lung cancer as a result of this exposure. [h] At five cigarettes per day, the active smoker suffers a roughly fivefold increase in risk of dying from lung cancer, compared to the "spontaneous" incidence.

The likelihood that otherwise healthy nonsmokers are being damaged by inhaling other people's smoke, coupled with the certainty that passive smoking is harmful to persons unfortunate enough to be allergic to tobacco smoke or suffering from a variety of preexisting diseases, make society's tolerance for public smoking in an era of growing environmental concern an ever more striking anomaly. As of 1976, the state of California, New York City, and a few other major political entities had passed laws restricting smoking in public buildings and public transportation systems. These measures are a good beginning, but there is ample reason to go much further. In situations where nonsmokers literally have no escape (such as on buses and aircraft, whose ventilation systems are incapable of maintaining a real distinction between smoking and no-smoking zones), smoking should long ago have been banned outright.

There is no doubt, of course, that voluntary smoking provides a great many people with a great deal of pleasure. But it seems to us that this activity should be legally confined, as certain other pleasurable (and considerably less dangerous) activities are, to consenting adults in private.

[h] Tinker, *Should public smoking be banned?*

It has become evident in the 1970s that in some regions the ambient air-quality standards cannot be met within the foreseeable future solely by progressively tightening emissions standards. The emissions characteristics of vehicles and other fuel-burners now in existence can be modified only so far by the addition of retrofitted control devices. The cleanest fuels -- low-sulfur coal,

low-sulfur oil, and natural gas -- are those in shortest supply (see Chapter 8). The rate at which new, cleaner engines and power plants replace old ones is limited, and further drastic reduction of new-source emission standards will require time-consuming technical transitions (e.g., to radically different automobile engines and to gasification or liquefaction prior to combustion of Coal). [25]

Several control strategies other than emissions standards have been discussed by government agencies, and some have been tried. They include: (1) "transportation control" schemes to reduce automobile use in urban areas, for example, by making parking more expensive or by making alternative transportation available; and (2) control by land-use regulations of the siting of indirect sources -- facilities such as shopping centers, stadiums, and airports -- which attract large numbers of vehicles and thus induce air-pollution problems.

A particularly vigorous controversy was underway in the mid-1970s on the issue of "significant deterioration" of air quality. Court decisions in 1972 and 1973 held that, under the *Clean Air Act*, no state could permit significant deterioration of air quality in areas where it was already cleaner than required by ambient standards. Industry spokespersons argued that this ruling amounted to arbitrary and capricious land-use regulations, effectively prohibiting further industrial development. Regulations issued by EPA in 1974 to comply with the court ruling were a compromise, identifying three classifications of areas: Class I, where air quality would be protected at existing levels; Class II, where moderate increases in pollution levels would be permitted; and Class III, where growth could proceed until air pollution reached national standards. Governors could determine how regions within their states were to be classified.

These regulations have been challenged both by industrialists as too severe and by environmentalists as too lenient. [26]

Urban Air Pollution: A Case History

Four centuries ago, Juan Rodriguez Cabrillo recorded in his diary that smoke from Indian fires in the Los Angeles basin rose for a few hundred feet and then spread to blanket the valley with haze. Because of this phenomenon, he named what is today called San Pedro Bay, the Bay of Smokes. Cabrillo was observing the effect of a thermal inversion. Normally, the temperature of the atmosphere decreases steadily with increased altitude, but during an inversion a layer of warm air overlies cooler air below and severely limits the vertical mixing of the atmosphere, and pollutants accumulate in the layer of air trapped near Earth's surface (Figure 10-3; see also Chapter 2). Because of the wind patterns in the eastern Pacific and the ring of mountains surrounding the Los Angeles basin, it is an ideal place for the formation of inversions, usually at about 2000 feet above the floor of the basin. In the basin, they occur on about 7 out of every 16 days.

Los Angeles has abundant sunshine, another climatic feature that contributes to its air-pollution problems. Sunlight acts on a mixture of oxygen, nitrogen oxides, and hydrocarbons to produce photochemical smog. Combustion products from well over 3 million cars are expelled into the atmosphere of the Los Angeles basin in addition to the wastes discharged by oil refineries and other industries. As a result, the air breathed by residents of Los Angeles contains far more than

the usual mixture of nitrogen, oxygen, and carbon dioxide -- it also contains carbon monoxide, ozone, aldehydes, ketones, alcohols, acids, ethers, peroxyacetyl nitrates and nitrites, alkyl nitrates and nitrites, benzpyrene, and many other dangerous chemicals.

Smog first became prominent in Los Angeles during World War II. Since then the Los Angeles County Air

[25]See, for example, Lees et al. *Smog*; Jet Propulsion Laboratory, *Should we have new engine? An automobile power systems evaluation*.

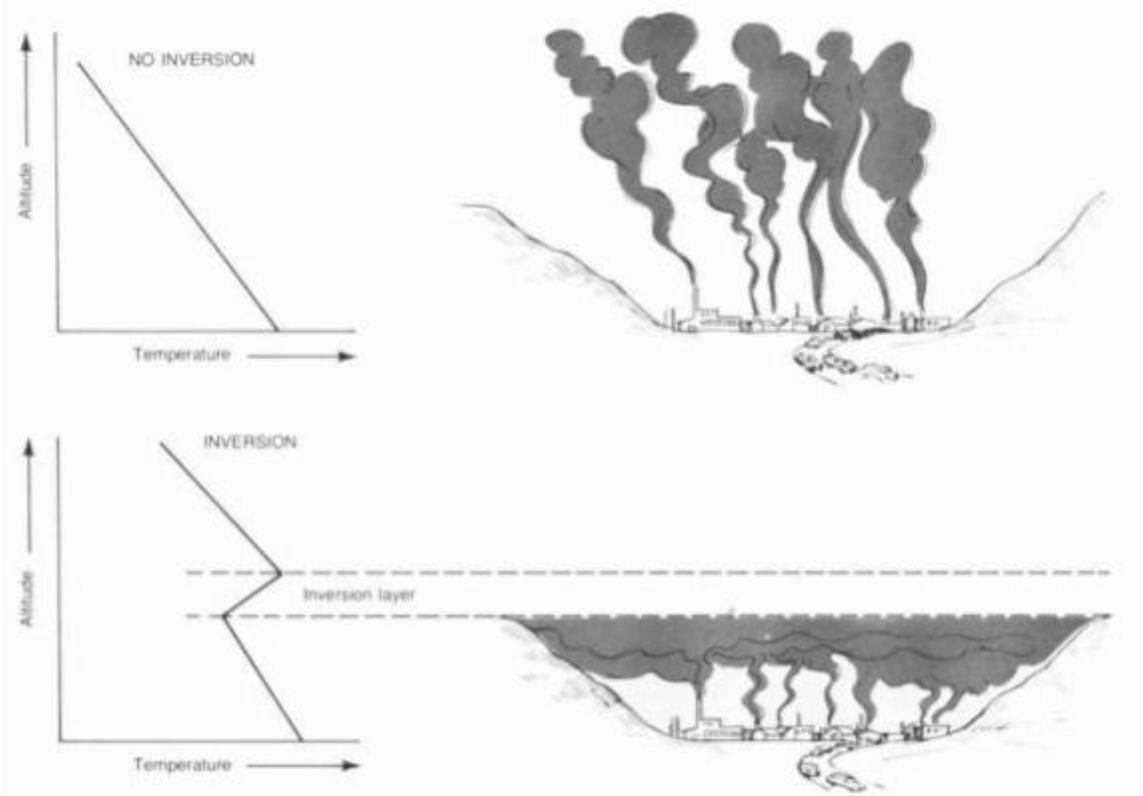

FIGURE 10-3 Temperature inversion, in which a layer of warm air overlies a layer of cooler air, trapping air pollution close to the ground.

Pollution Control District (APCD) has pursued a vigorous policy of smog abatement. The district has imposed strict controls on industry, setting rigid emission standards for power plants, refineries, and other sources of pollution. Some 1.5 million domestic incinerators, a dozen large municipal incinerators, 57 open-burning dumps, and incinerators in commercial buildings have been eliminated. Coal-burning has been made illegal, and so has (for most of the year) the burning of oil with a high sulfur content. Control is exercised over the escape of vapors from petroleum storage tanks and gasolineloading facilities. Also controlled are commercial processes that require organic solvents, the olefin content of gasoline sold in Los Angeles County, and many other contributors to air pollution. Furthermore, all cars sold in California were required to

have smog-control devices designed to reduce crankcase emissions of hydrocarbons before the devices were required nationwide. [27]

The Los Angeles area also has partially "controlled" its smog by generating a portion of its electricity in areas of low population in New Mexico and Nevada, using low-quality coal that would not be tolerated under the air-quality laws of California or Arizona. This is roughly equivalent to throwing garbage in a neighbor's yard because his yard is larger and he is powerless to prevent it. It is worth pondering whether the "necessity" of exporting pollution this way from areas of high population density and affluence might not indicate something about the desirability of further growth in those areas.

---

[27] For details on the history and prospects of the Los Angeles situation, see, for example, Lees et al. *Smog*.

WATER POLLUTION

Water pollutants take many forms. One useful classification follows: [28]

Disease-causing organisms--specifically parasites, bacteria, and viruses, which often enter water with human sewage;
Synthetic organic compounds in the form of industrial, household, and agricultural chemicals, as well as water-treatment chemicals added deliberately and the products formed by the reaction of these with other contaminants;
Inorganic compounds and mineral substances, including acids, mineral fibers such as asbestos, and heavy metals, discharged directly into water by certain mining and industrial operations and also entering water as fallout or in precipitation from the atmosphere;
Radioactive substances from commercial and military applications of nuclear energy;
Oxygen-demanding wastes--namely, organic compounds contained in sewage and some industrial effluents, whose biological or chemical degradation depletes dissolved oxygen;
Plant nutrients, such as nitrogen and phosphorus, from sewage and agricultural runoff;
Sediments from erosion caused by agriculture or construction;
Thermal discharges from power plants and certain industrial facilities.

Water pollutants also can be classified by their effects: direct impact on health in the form of bacterial or viral disease; production of cancer, genetic defects, and birth defects; other varieties of acute and chronic toxicity to people; [29] and effects on ecosystems, through which an impact on human beings may subsequently be felt.

This section of text gives an overview of sources, degree, and treatment of water pollution. Pesticides, radioactivity, fluorides, and heavy metals (which occur in air and soil as well as in water) are treated in more detail later in this chapter. These and other water pollutants receive further attention in the discussions of carcinogens and mutagens. Effects on ecosystems, especially the impacts of Items 5 through 8 in the above list, are discussed in Chapter 11.

Sources and Degrees of Water Pollution

Approximately one-third of waste water in the United States comes from households and two-thirds from commerce and industry. [30] The most commonly used index of pollution is *biochemical oxygen demand* (BOD), which refers to the quantity of oxygen required by bacteria to oxidize organic waste aerobically to carbon dioxide and water. A standard measure of BOD in practice is the amount of oxygen used in the first five days of decomposition at 20° C; this is called BOD5. Domestic sewage typically has a BOD5 of around 200 milligrams of oxygen per liter, and that for industrial waste may reach several thousand milligrams per liter. [31] A BOD of 0.17 pound, or 77 grams, is sometimes called a *population equivalent*, being roughly equal to the daily requirement for the domestic wastes of one person. When commercial and industrial wastes are added in, there are about 3 population equivalents of BOD actually produced per person in the United States--that is, a requirement of 0.5 pound, or 230 grams, of dissolved oxygen per person per day. The capacity of a sewage treatment plant is generally measured in population equivalents per day.

Contamination of water by sewage is the principal cause of water-borne disease, including cholera, typhoid and paratyphoid fever, dysentery, and infectious hepatitis. The cause-and-effect relation became evident gradually in the course of a series of major epidemics of cholera and typhoid fever in England, Germany, and the United States between 1850 and 1900. In each of these, certain cities or parts of cities were struck heavily while adjacent areas escaped relatively lightly. Invariably the epidemicstricken areas obtained their water from different wells or different stretches of river than the areas that escaped, so

---

[28] Modified slightly from G. M. Masters, *Introduction to environmental science and technology*, chapter 5.

[29] It is worth noting that absence of certain contaminants in water may also be harmful. Persons whose drinking water is soft (low in dissolved minerals) have a higher incidence of cardiovascular disease than persons who drink hard water. (See H. Hudson and F. Gilcreas, *Health and economic aspects of water hardness and corrosiveness*; L. C. Neri et al., *Health aspects of hard and soft waters*.)

the evidence that the crucial difference was contamination with sewage eventually became overwhelming. [32]

BOD, although a rough measure of the quality of waste, does not accurately indicate the risk of disease; for that, more specific indices are required. One of the most common is the number of coliform bacteria (sometimes, more specifically, fecal coliforms--intestinal bacteria, especially of the genus *Escherichia*, found in feces) per unit volume of water. Although the bacteria are themselves relatively harmless, their presence in large numbers indicates that pathogens are probably present as well; conversely, their absence is a good, although not perfect, indication that pathogens are absent. United States Public Health Service (USPHS) drinking-water standards for coliform organisms specify that the most probable number (MPN) shall not exceed I coliform organism per 100 milliliters of water. (The MPN is determined by culturing a series of samples from the water supply in a medium favorable to the growth of coliform bacteria.) Standards recommended by the Environmental Protection Agency for water-contact recreational activities specify MPNs of 10,000 total coliforms or 2000 fecal coliforms per 100 milliliters. [33] The latter coliform criteria are those typically used when a beach is closed because of pollution.

Table 10-5 shows water-quality trends in the United States between 1963 and 1972, measured against standards of coliform bacteria and other indicators, for a sample of "reaches" covering major parts of the inland waters of the country. As the table indicates, water quality in the United States in this period was improving in some respects but deteriorating in others.

Even after processing in municipal water-treatment plants, the water supplied for drinking in cities in the United States is not always safe. There is some evidence, for example, that a high content of organic matter in water can somehow protect viruses from the disinfective effects of the chlorine heavily used in municipal water treatment. [34] Infectious hepatitis is spreading at an alarming rate in the United States, and a major suspect for the route of transmission is the "toilet-to-mouth pipeline" of water systems not made safe by chlorination. [35] The total incidence of water-borne diseases in the United States dropped steadily from the 1930s to the mid-1960s but then started to rise again; the reasons for the upturn are not known in detail. [36]

The safety of chlorine itself as an ingredient of water treatment has been questioned on the grounds that it may interact with other chemicals in water to form mutagenic and carcinogenic compounds. [37] Whatever the cause, there are suspicious correlations between drinking-water sources and cancer deaths. [38]

Another direct health hazard is nitrate pollution. The heavy use of inorganic fertilizers in agriculture results in

[37]See, for example, R. Tardiff and M. Deinzer, *Toxicity of organic compounds in drinking water*; J. L. Marx, *Drinking water: another source of carcinogens?*; and the sections on carcinogens and mutagens below.
[38]Page et al., *Drinking water and cancer mortality in Louisiana*.

the flow of a heavy load of nitrates into water supplies; nitrates also accumulate in high concentrations in crops. Nitrates themselves are not especially dangerous, but when certain bacteria are present in the digestive tract, they may convert the nitrates into highly toxic nitrites. Farm animals and human infants are particularly likely to have in their digestive tracts these types of bacteria as well as the appropriate conditions for the conversion of nitrate to nitrite. In addition, conversion of nitrates to nitrites can occur in any opened container of food, even if it is subsequently refrigerated. Nitrate water pollution in lakes, streams, and wells probably is most dangerous in the Central Valley of California, where it is a severe public-health hazard and where doctors often recommend that infants be given only pure bottled water. It is also serious, however, in such other states as Illinois, Wisconsin, and Missouri. [39]

Treatment of Water and Sewage

Water-treatment plants are those used to bring "raw" water (e.g., from rivers and reservoirs) up to drinkingwater quality. Sewage-treatment plants are intended to bring domestic and industrial waste up to a quality suitable for discharge into rivers, lakes, or coastal waters.

The main steps in typical water-treatment plants are coagulation, settling, and filtration to remove suspended particles, aeration to remove the volatile substances most responsible for taste and odor, and chlorination to kill pathogenic organisms. The coagulant, often alum [$Al_2(SO_4)_3 \cdot 18H_2O$], enables colloidal particles to stick together when they encounter one another; *flocculation* refers to the agglomeration of submicroscopic coagulated particles into larger ones that settle out or that can be readily filtered. The filter is generally sand and gravel. These treatment processes are ineffective for removing dissolved solids, which exceed the recommended concentration of 500 milligrams per liter in many American communities. [40] These can be partly removed by more expensive chemical techniques (water softening) or by physical desalting processes. The latter are very expensive and are not widely employed (see also Chapter 6).

There is a wide variety of possibilities for the treatment of sewage. In 1970, about 73 percent of the population of the United States was served by sanitary sewer systems; the remaining 27 percent relied on cesspools and septic tanks. [41] Of the roughly 150 million people served by sewers, the output of about 10 million people was discharged to the environment untreated (raw sewage); the output of 40 million received what is called primary treatment; and that of 100 million received primary and secondary treatment.

Primary treatment consists of mechanical filtration, screening, and settling, followed by chlorination. It removes 50 to 65 percent of the suspended solids and 25 to 40 percent of the 5-day BOD. The products are a solid sludge and a liquid effluent that is not suitable for any direct reuse; only where the receptacle is the open ocean can primary treatment alone possibly be considered adequate. The cost of such treatment is 4 to 5 cents per 1000 gallons (including the construction cost of the facilities), and the electricity cost of operation is in the range of 10 to 20 kilowatt hours per year per population equivalent of capacity. [42]

Secondary treatment adds to primary treatment (minus the chlorination) a set of biological processes similar to the decomposition processes that occur in nature; that is, the organic wastes are transformed by bacteria in the treatment plant, where oxygen is provided by aeration, instead of depleting dissolved oxygen in the receiving waters. The sludge from this process, consisting largely of bacterial masses, is concentrated and processed further in an anaerobic digester. Here most of the material is converted into carbon dioxide and methane (CH_4), the latter being collectible for use as fuel in the sewage plant or elsewhere (see also Chapter 8). The remaining solids are dried and can be used for fertilizer or landfill. Secondary treatment removes about 90 percent each of the 5-day BOD and the suspended solids. The liquid effluent is suitable for industrial reuse and, in some circumstances, for irrigation. The cost of treatment up to

[39] See, for example, N. Gruener and R. Toeplitz, *The effect of changes in nitrate concentration in drinking water on methemoglobin levels in infants*; and National Academy of Sciences, *Accumulation of nitrate*.

[40] Masters, *Introduction to environmental science*, p. 151.

[41] These and succeeding data in this paragraph are from U.S. Environmental Protection Agency, *The economics of clean water, summary*.

[42] See, for example, American Chemical Society, *Cleaning our environment: The chemical basis for action*; or Eric Hirst, *The energy cost of pollution control*.

the secondary level (including the primary step) is 8 to 15 cents per 1000 gallons, and the electricity consumption is 30 to 70 kilowatt hours per year per population equivalent. A major defect of secondary treatment is the low degree of removal of nutrients, which is typically around 50 percent of the nitrogen and 30 percent of the phosphorus. The high nutrient concentrations remaining in the effluent from secondary treatment contribute heavily to the eutrophication problems described in Chapter 11.

Tertiary treatment of sewage was in use in the early 1970s for only a tiny fraction of the U.S. population, but it is receiving increased attention because of growing interest in eutrophication

and in direct reuse of waste water. The idea is to remove 97 to 99 percent or more of the BOD, 90 percent or more of the phosphorus, and as much as possible of complex organics and nitrogen. There is an enormous variety of tertiary-treatment technologies addressed to those goals, including physical, chemical, and biological processes. [43] Among the tertiary processes used in different combinations in different plants are distillation, reverse osmosis, electrodialysis, chemical precipitation, ion exchange, and carbon adsorption. Tertiary treatment is expensive (17 to 54 cents per 1000 gallons) and electricity-intensive (66 kilowatt hours per year per population equivalent in the most well-known operative plant, at South Lake Tahoe, California). The effluent from successful tertiary treatment can be used for irrigating food crops, for recreation, and perhaps (say the advocates of some processes) for direct human consumption. Lack of understanding of the circumstances in which pathogenic viruses and toxic chemicals survive treatment makes it difficult to rely on producing pure drinking water this way, however. [43a]

Relation to Population

Water pollution from sewage provides one of the classic examples of the diseconomies of scale accompanying population growth. If a few people per mile live along a large river, their sewage may be dumped directly into the river and natural purification will occur. But if the population increases, the waste-degrading ability of the river becomes strained, and either the sewage or the intake water must be treated if the river water is to be safe for drinking. Should the population along the river increase further, more and more elaborate and expensive treatment will be required to keep the water safe for human use and to maintain desirable fishes and shellfishes in the river. In general, the more people there are living in a watershed, the higher are the per-capita costs of avoiding water pollution.

As the populations of many municipalities grow, their sewage-treatment facilities, though once adequate, may be outgrown. Funds for new sewage facilities can be obtained only at the expense of funds needed for more and better schools, police departments, water systems, roads, and other public services. Inevitably, it seems, the available funds are insufficient to meet all of these needs, which are created, in part, by increases in population. The sewage problem is increased by lax inspection and lax enforcement of public-health standards, which permit construction of septic tanks too close together or in unsuitable soils in many of the rural and suburban areas where there are no general sewage facilities.

Novel Approaches

The expense in dollars and energy to cope with expanding sewage-treatment needs with ever-moresophisticated tertiary-treatment facilities has led some people to think seriously about and to develop alternative approaches. One that is widely regarded in the conventional sewage-treatment fraternity as heresy, but that has achieved notable success in several major installations, is "land treatment." The three basic varieties of this approach are rapid infiltration through porous surface layers into deeper aquifers, crop irrigation by overland flow, and crop irrigation by slow infiltration. In all three, one starts with the effluent from secondary treatment, and the idea is to let natural processes (rather than expensive technological replacements) do the rest. Of course, there are many circumstances where the population is so dense or the particular chemical pollutants so refractory that natural processes could not handle the

[43]For details, see, for example, ACS, *Cleaning* and Masters, *Introduction to environmental science*, pp. 160-163.
[43a]Sobsey M. D., *Enteric viruses and drinking-water supplies*.

load. It has been argued that the high cost of tertiary treatment points up the disadvantages of so overburdening natural processes that they must be replaced completely by technology. [44] We agree.

An alternative approach to sewage treatment that is already in use in the United States and several other countries is ponding with algae. The waste water is introduced into large, shallow ponds, where bacteria populations maintained for the purpose ingest the dissolved organic material and convert it to carbon dioxide and water. Algae in the ponds use the carbon dioxide together with nutrients present in the waste water to produce biomass, which may be harvested and dried for use as animal feed or fuel. The oxygen produced by the algae as a product of photosynthesis is utilized by the bacteria in metabolizing the waste materials, completing the symbiosis. [45] A disadvantage shared by this approach and land treatment is their relatively large requirement for land area.

Yet another approach to the sewage problem is to mount an attack closer to the source. The average American family flushes about 35,000 gallons per year down its toilet, which is both a drain on municipal water supplies and a strain on municipal sewage treatment. [46] A variety of improvements has been suggested, from reducing the water use by placing bricks in the tank (only a partial solution to part of the problem) to several novel toilets that incinerate or compost what they collect. The one receiving the most attention is the Swedish *clivus multrum*, which composts wastes without water, electricity, or chemicals, wafts odors out a chimney on the roof, and needs little maintenance.

Perhaps it is time, in view of recent developments in composting toilets, land treatment and ponding for sewage-plant effluent, and biogasification (see Chapter 8) to rethink the entire sewage system.

Beyond Sewage

Even complete and effective treatment of sewage, if that could be achieved, would leave many waterpollution problems untouched. Many industries discharge wastes directly into waterways; such discharges must be controlled on a plant-by-plant basis. Runoff from agricultural lands carries the residues of pesticides and fertilizers. Storm sewers not connected to sewagetreatment systems carry a heavy burden of hydrocarbons and heavy metals washed from city streets into waterways. Such so-called area sources (as distinct from point sources) are especially difficult to control. As far as at least the heavy metals are concerned, the best control would seem to be to prevent their emission in the first place; a major step toward this is the elimination of tetraethyl lead in gasoline. Many water pollutants other than heavy metals also originate as air pollutants. Nitrates and sulfates, for example, fall in the rain, having been emitted as oxides of nitrogen and sulfur. In this instance, water pollution control means air pollution control. Some other very

serious forms of water pollution have their origins in solid wastes accumulating on the land: for example, tailings from mines of various kinds, and sludges from industrial processes (including some air-pollution control measures that produce sludges). Finding ways to stabilize these solids so they do not contaminate water supplies is difficult. The problem of acid drainage from coal mines is particularly serious and widespread, and apparently destined to increase substantially as reliance on coal as an energy source grows (see also Chapter 8).

Regulation of Water Pollution

The history of water-pollution abatement in the United States has resembled that of air pollution--generally too little effort applied too late. Prior to 1972, the federal approach to control of water pollution was defined by the *Federal Water Pollution Control Act (FWPCA) of 1948* and the *Refuse Act of 1899*. Under the *FWPCA*, enforcement of regulations was so slow and cumbersome as to be almost nonexistent. A *Supreme Court interpretation of the Refuse Act* in 1960 improved matters somewhat, holding that the government could sue industries to stop their discharges into navigable waterways. A national system of discharge permits was later set up under the jurisdiction of the Army Corps of

[44]For a good discussion of "land treatment" in this context, see Jeff Stansbury , *Of human waste and human folly*.
[45]W. J. Oswald, *Engineering applications*; Metcalf and Eddy, Inc., *Wastewater engineering*.
[46]Sam Love, *An idea in need of rethinking: the flush toilet*.

Engineers and the Environmental Protection Agency, but it was never fully implemented. [47]

In 1972, Congress passed amendments to the *FWPCA*, requiring that all polluters obtain "permits" from the EPA that limit amounts and constituents of material to be discharged. Progressively tightened emission standards for industrial and municipal discharges were called for, with important deadlines in 1977 and 1983. The 1972 amendments also provided for an increase in federal aid to local governments for the construction of municipal waste-treatment plants ($18 billion was authorized over a 3-year period). Effluent guidelines set up under the amendments since 1972 have been challenged in many lawsuits by the industries affected, while some environmentalists have complained that the discharge permits in practice are simply "licenses to pollute" that do not serve the spirit of the law. [48] There had nevertheless been some improvement in water quality in many areas by 1977. The establishment of standards with deadlines has simplified the problems both of polluters in controlling their effluents and of government agencies in carrying out regulatory functions. [48a]

Prior to 1974, the monitoring of municipal water supplies for drinking safety was in the hands of the Public Health Service, which was empowered only to set standards to prevent the introduction and spread of disease organisms. The myriad of dangerous and possibly dangerous chemicals appearing in increasing quantities in U.S. drinking-water supplies went largely unregulated. *The Safe Drinking Water Act*, which became effective in December of 1974, requires that EPA promulgate primary drinking-water standards (regulating substances with

adverse impact on human health) and secondary standards (regulating nonhealth effects, such as taste and odor). Primary standards were to be in effect in interim form by December 1976 and in final form by September 1977. Enforcement authority will be mainly in the hands of individual states. Another provision of the 1974 act gives the administration of EPA authority to block underground waste-disposal practices that threaten aquifers used for drinking water and to stop federal funding of any other projects that may threaten such aquifers. [49]

The Ocean Dumping Act of 1972 regulates dumping by American ships and other ships leaving U.S. ports. Jurisdiction is divided among EPA, the Secretary of the Army, and the Coast Guard. Sewage sludge was a major component of the material being dumped in the mid1970s, most of it accounted for by the activities of Philadelphia and New York City off the Atlantic coast. If the EPA succeeds in halting this dumping, it will aggravate an already difficult problem of on-land disposal for rising amounts of sludge.

PESTICIDES AND RELATED COMPOUNDS

Prevalence

The public is exposed to some substances, such as chlorinated hydrocarbons, lead, mercury, and fluorides, in so many ways that these must be considered general pollutants. Chlorinated hydrocarbons are among the most ubiquitous manufactured chemicals in the environment. Of these, dichlorodiphenyltrichloroethane [50] or DDT (Figure 104) has been employed the longest, having been put into mass use late in World War II. It is the most commonly used and most thoroughly studied of all synthetic insecticides. DDT, together with its breakdown products DDE and DDD (TDE), often occurs in concentrations of more than 12 parts per million (ppm) in human fat, and as high as 5 ppm in human milk (though the usual range is some 0.05 to 0.26 parts per million). [51]

[48a] John R. Quarles, *National water quality: Assessing the mid-course correction*.

[49] CEQ, *Environmental quality*, 1975, pp. 76-77.

[50] DDT is dichlorodiphenyltrichloro-ethane. DDT is often metabolized to DDE, dichloro-diphenyl-dichloro-ethylene, and DDD (TDE), dichloro-diphenyl-dichloro-ethane. DDT, DDE, and DDD are often lumped together in residue studies as DDT-R or "total DDT." These compounds are very similar in structure to other pesticides such as methoxychlor and kelthane (see Appendix 3; R. D. O'Brien, *Insecticides: Action and metabolism*; and J. Capizzi and J. M. Wite, eds., *Pesticides, pest control, and safety on forest and range lands*.)

[51] See, for example, for fat, James E. Burns, *Organochlorine pesticide and polychlorinated biphenyl residues in biopsied human adipose tissue, Texas, 1969-1972*; and National Academy of Sciences (NAS) *Contemporary pest control practices and prospects: The report of the executive committee*. For milk, see E. P. Savage et al., *Organochlorine pesticide residues and polychlorinated biphenyls in human milk*, Colorado, 19711972, and references therein.

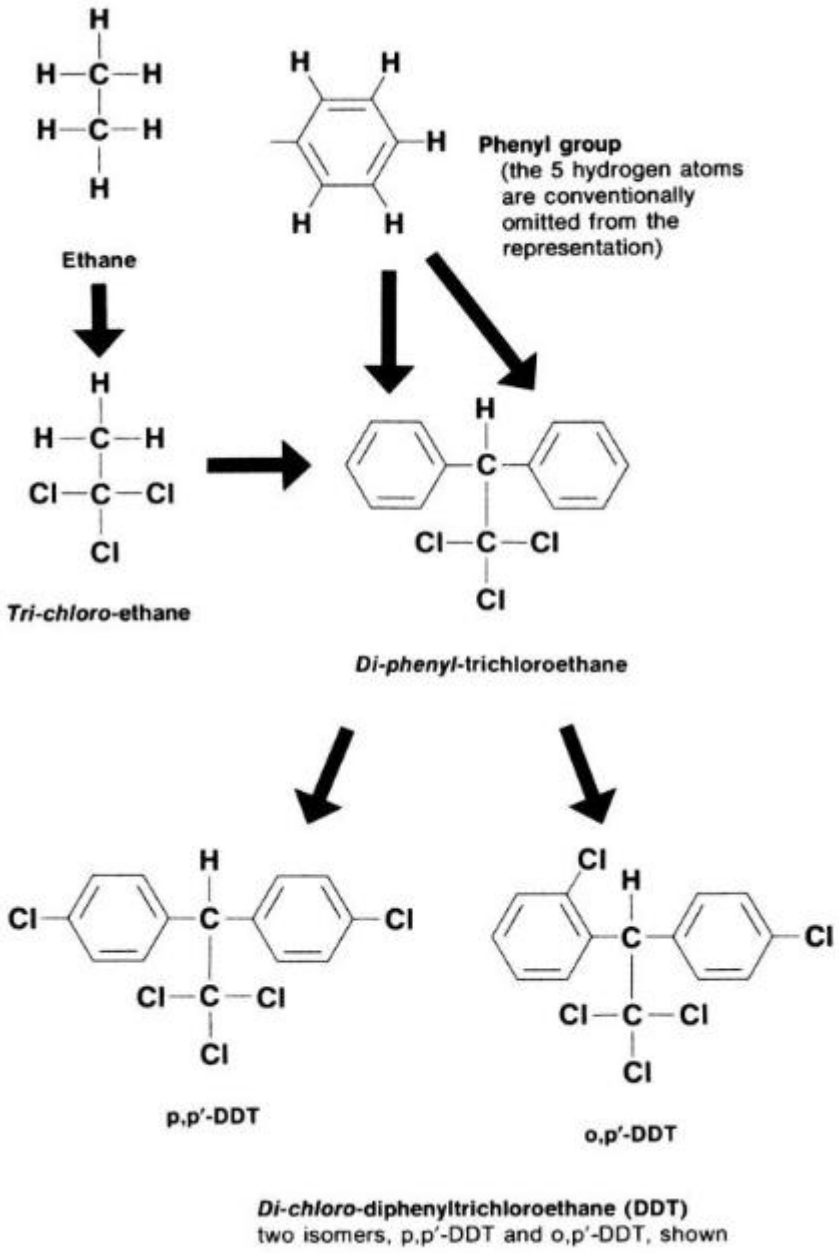

FIGURE 10-4

The structure and name of DDT. The long, complex name indicates the structure of the molecule based on the simple two-carbon organic compound ethane (C_2H_6) found in natural gas. Three chlorine atoms are substituted for the three hydrogens bonded to one carbon atom, and two phenyl groups (C_6H_5 radicals, benzene minus one hydrogen) are bonded to the other carbon of ethane. Chlorine atoms substitute for one hydrogen of each phenyl group. Two isomers (molecules composed of the same number and kinds of atoms but arranged differently) of DDT are shown. The p, p′ isomer has both chlorines in the "para" position, opposite the ethane carbon. The o, p′ isomer has one chlorine in the "ortho" position, adjacent to the carbon. Not shown is a ring with the chlorine in the *m* (meta) position, with one hydrogen between the carbon and the chlorine. (For a brief view of biological chemistry, see White, 1970.)

In the early 1970s most mother's milk in the United States contained so much DDT that it would have been declared illegal in interstate commerce; the permissible level in cow's milk is set by the FDA at 0.05 parts per million. Other chlorinated hydrocarbon insecticides, including aldrin, dieldrin, and benzene hexachloride (hexachlorobenzene--HCB), have also been found in human milk.

Recently there has been some tendency for total DDT levels (as well as those of other chlorinated hydrocarbons) to decline in human adipose (fat) tissues in the United States (Table 10-6), although there is great variation from study to study. [52] With the banning of almost all uses of DDT in 1972 and regulatory action against other chlorinated hydrocarbons following soon thereafter, it seems likely that residues of these chemicals in human tissues and milk will decline substantially in the late 1970s in the U.S. and in other nations that have reduced their use.

Another class of chlorinated hydrocarbon compounds, polychlorinated biphenyls (PCBs), has also been found to be a serious pollutant, showing up in human fat and milk. [53] These compounds are used in a variety of industrial processes and are released into the environment in a variety of ways. They vaporize from storage containers, are emitted from factory smokestacks, are dumped into rivers and lakes with industrial wastes, and, along with a variety of other hydrocarbons, are added to the load of particulate atmospheric pollutants as automobile tires are worn down. They get into food products through contact with paint and plastics, and through accidental contamination. For example, a shipment of 60,000 chicken eggs contaminated with PCBs reached consumers in 1971, after the hens had consumed contaminated fish meal. [54] The most serious foodcontamination episode involving PCBs was the Kanemi rice-oil (Yusho) disaster in Japan. More than 1000 people were stricken with horrible acne-like skin lesions (chloracne) and an array of other symptoms including vomiting, diarrhea, headaches, and visual disturbances,

after a heat-exchanger leaked PCBs into oil used in frying foods. [55]

Chlorinated hydrocarbons and other pesticides are present in very low concentrations in drinking water, in fruits and vegetables, and even in the air. Greater amounts are present in meat, fish, and poultry. [56] A summary of the average pesticide contents of foods tested between 1965 and 1970 is shown in Table 10-7. Averages, however, are not the whole story. At times the dosage is direct and high. Farmers sometimes far exceed legal residue levels of insecticides on their crops and get away with it, because inspection is inadequate. Some ill-informed grocers spray their produce to kill fruit flies. In the summer of 1968, our research group found leaking cans of chlordane dust (a chlorinated hydrocarbon insecticide) on a narrow shelf above the onion bin in a supermarket. The dust was present on the produce. The manager, on being informed, took prompt corrective action, but not before some of his customers had added to their loads of chlorinated hydrocarbons. By the summer of 1969, the pesticides had reappeared on the shelf over the produce, and complaints had to be renewed. Obviously, the sale of all pesticides should be prohibited in food stores.

A colleague of ours has observed massive antiroach spraying (presumably of chlordane) in a restaurant kitchen, where the spray drifted over exposed food. Some restaurants formerly used lindane vaporizers; fortunately these have now been banned. Regardless of whether such practices and the resultant heavy doses are common or not, continuous "light" exposure is virtually unavoidable.

Effects

Can low-level exposure be dangerous? Because of the variety of problems enumerated in Box 10-2, and others that we deal with below in the section on carcinogenesis, it has been very difficult to evaluate the long-term and chronic effects of pesticides. Biologists have long been warning that there is no evidence that DDT, even though its effects may not be immediately obvious, might not have subtle or long-term effects. In fact, there is every reason to believe that the biologically active molecules of DDT are dangerous. In 1962 Rachel Carson wrote, "For the population as a whole, we must be more concerned with the delayed effects of absorbing small amounts of the pesticides that invisibly contaminate our world." [56a] But often the possibility of subtle, chronic effects has been discounted by industry, ignored by the government, and forgotten by the public. That DDT has very low immediate toxicity to mammals, including human beings, has been known since it was first put in use, and this has never been questioned. Promoters of pesticides have even resorted to the dangerous extreme of eating spoonfuls of pure DDT in an effort to prove how harmless it is, but such actions in no way demonstrate

that DDT is safe for human consumption over the long run.

People can understand acute poisoning, but they find subtle and cumulative physiological changes difficult to grasp. Why should it matter if high concentrations of chlorinated hydrocarbons are being stored in their bodies? Years ago, a study of workers in a DDT plant and another done with convicts purported to show that no ill effects resulted from heavy exposure. [57] But those two studies were poorly designed and utterly inadequate to assure the long-term safety of DDT when introduced into the *entire human population*. Both were done with people whose first exposure occurred as *adults*, and the convict study followed individuals for *less than two years*. The study of exposed workers did not investigate what had happened to workers who were no longer employed. The effects on the delicate developmental systems of fetuses and infants were not investigated; nor were there any women or children in the study. No attempt was made to investigate the possible effects of DDT exposure on large populations over several decades, and the causes of death in large numbers of people with high and low exposures were not statistically compared.

Biologists have just started to get an inkling of what that "harmless" chlorinated hydrocarbon load may be doing to people over the long run. Animal studies give some clues. In high doses, DDT and some other chlorinated hydrocarbons--aldrin, dieldrin and endrin--have

[57] W. J. Hayes, Jr. et al., *The effects of known repeated oral doses of chlorophenothane (DDT) in man*; E. R. Laws et. al., *Men with intensive occupational exposure to DDT*. A more recent study by E. R. Laws et al., *Long-term occupational exposure to DDT, deals with a very small group of men* (35), but does indicate at least that DDT is not as potent a carcinogen as some other known causes of occupational cancers.

been shown to increase the incidence of cancers, especially liver cancers, in mice. This indicated that they might also be carcinogenic in human beings. However, these chemicals at some doses stimulate enzyme systems (mixed-function oxidizing enzymes) which metabolize not only the chlorinated hydrocarbons but also other carcinogens. Thus, their relationship to cancer may be very complex, and studies to date cannot be considered conclusive. [58] But, overall it seems clear that human contact with the pesticides should be minimized.

It must be made clear that only a small minority of the pesticides tested are in any way implicated in carcinogenesis. In studies of 120 different compounds, 11 pesticides were judged carcinogenic, but 89 (73 pesticides) showed no significant indications of carcinogenicity (20 compounds were questionable). [59] Since the compounds tested were chosen as likely carcinogens a priori on the basis of their chemical structure or other prior indications of possible carcinogenicity, the findings are conservative. The National Academy of Sciences 1976 study of pest-control practices estimates that an upper limit on the proportion of currently used pesticides that may cause cancers in human beings is about 25 percent. [60] This is not necessarily much cause for cheer, since DDT and other widespread compounds have been implicated -- and a generation of people that have been exposed to DDT and its relatives since before they were born is now maturing. [61]

Other investigations have produced ominous results. One study, in which data were obtained by autopsies, showed a correlation between DDT levels in fat tissue and cause of death. Concentrations of DDT and its breakdown products, DDE and DDD, as well as dieldrin (another chlorinated-hydrocarbon pesticide), were significantly higher in the fat of patients who died of softening of the brain, cerebral hemorrhage, hypertension, portal cirrhosis of the liver, and various cancers than in groups of patients who died of infectious diseases. The histories of the patients in the study showed that concentrations of DDT and its breakdown products in their fat were strongly correlated with home use of pesticides, heavy users having much higher concentrations than light or moderate users. [62]

More conclusive investigations of these effects are urgently needed, but in the light of what is known about the deleterious effects of chlorinated hydrocarbons on laboratory animals, the results of this study alone leave little room for complacency. Neurophysiologists have established that DDT has irreversible effects on impulse conduction in nerve cells. It is not surprising, therefore, that several studies implicate DDT in the disturbance of nervous-system function. Effects on EEG (brain wave) patterns have been shown; trout exposed to 20 parts per *billion* DDT showed a loss of learning ability. [63] Finally, the behavior of larval marine crustaceans (locomotion, etc.,) is significantly affected at concentrations below 200 parts per trillion (ppt). [64]

As indicated above, there is evidence that the amount of DDT stored in human tissues has not increased for the past decade or so in the United States, and may be declining. At a given exposure level, it apparently takes about one year for an equilibrium to be established between intake and loss through excretion and breakdown, after which continued exposure produces no increase in DDT storage. [65] The mean concentration of DDT in human populations varies widely from one geographic location to another, both within and between countries. It also varies with diet, race, age, and undetermined individual differences. For reasons that are not entirely clear, the black population has a much higher average level of DDT concentration in the blood than does the white population. It is possible that this is a "poverty effect" due to greater home use in attempts to control roaches; it might also be a dietary effect. Aboveaverage DDT levels in blacks includes those who live in cities, as well as farm workers who might be expected to have more than average exposure to insecticides. Table 10-8 shows the DDT concentrations that have been

found in a series of studies done at different times and places.

Generally, people in the most northern countries, where growing seasons are short and insects are not a year-round problem, have substantially smaller DDT burdens than people in the United States. Intensive agriculture in Israel, as well as increased household use of pesticides, is probably responsible for the high levels found there. Unfortunately, reports of DDT loads from other countries with intensive agriculture, such as Japan and the Netherlands, are not available. High levels in Delhi, India, may be related to the use of DDT to preserve stored food.

In a study of individuals from Dade County, Florida, a significantly lower DDT-DDE concentration was found in children under 5 years of age, suggesting that they had not yet reached their equilibrium levels. Six stillbirths and fetuses were examined and found to have loads more closely reflecting concentrations in their mothers' tissues. Passage of DDT across the placental membrane into the fetus has now been demonstrated to take place as early as The 22nd week of pregnancy, and may occur well in advance of that. [66]

Studies in dogs show that DDT storage concentrations rise dramatically if aldrin, another chlorinated-hydrocarbon insecticide, is also ingested. [67] This is another example of synergism between pollutants, about which too little is known. Whether aldrin also affects DDT storage concentrations in human beings is not known, but it is certainly possible.

Other studies have shown that certain anticonvulsant drugs can act to reduce DDT concentrations in blood and fat tissues of people. [68] Nothing is known about how this occurs or what long-term side effects may follow the use of these drugs for DDT reduction. As long as DDT is ubiquitous, the treatment would be only temporary, unless the drugs were taken frequently or continuously.

It is difficult at this juncture to evaluate the magnitude of the direct threat to human health represented by present levels of chlorinated-hydrocarbon contamination. Most analyses have dealt with DDT, although human beings are also being exposed to a wide range of related compounds, some of which have considerably higher immediate toxicity. There are indications that dieldrin, perhaps four times as toxic as DDT, may be involved in portal cirrhosis of the liver, and that benzene hexachloride may contribute to liver cancer. Furthermore, almost nothing is known about synergistic interactions between chlorinated hydrocarbons, or between these chemicals and other drugs and environmental contaminants. [69] The critical question, we reiterate, is not immediate toxicity, but *long-term effects*. The oldest people who have been exposed to high concentrations of DDT since conception reached the age of thirty in 1976. It is possible that their life expectancies already have been greatly reduced; it is also possible that there will be no significant reduction. No one will know until more time has passed.

At any rate, humanity will eventually find out what the overall effects of the chlorinated-hydrocarbon load are,

[66]Fiscrova-Bergerova et al., *Levels of chlorinated hydrocarbons*.

[69]See, for example, A. H. Connery and J. J. Burns, "Metabolic interactions among environmental chemicals and drugs".

since the persistence of these compounds guarantees decades of further exposure even after their use has been discontinued. The continued release of chlorinated hydrocarbons into the environment is tantamount to a reckless global experiment, and all human beings -- as well as all other animals that live on Earth -- are playing the role of guinea pigs.

In 1972, a ban on DDT for almost all uses in the United States was imposed by the U.S. Environmental Protection Agency. (The regulation of pesticides is discussed in detail in Chapter 14 as a case study of the interaction of economics and environment in the political arena.) Concern has been expressed that banning of chlorinated hydrocarbons would lead to increased immediate mortality from pesticides, because the organophosphate compounds that would be used to replace DDT, although they are much less persistent and presumably present a relatively small long-term risk, have a higher acute toxicity. But around 1969 occupational deaths from pesticides (mainly organophosphates) ran about 12 per year nationally, and there has been no sign of an increase. [70]

In the most spectacular recent episode of acute toxicity involving a pesticide in the United States, the guilty agent was a complex chlorinated hydrocarbon, kepone. Thirty persons working in the plant producing this insecticide-fungicide were hospitalized with tremors, blurred vision, loss of memory, and a threat of such long-term effects as sterility and cancer. [71]

One organophosphate, leptophos, which has not been approved by the EPA for use in the U.S. but is marketed abroad, apparently causes delayed neurological damage rather than immediate illness. Victims of organophosphate poisoning, if they survive, usually recover completely. The delayed neuropathy caused by leptophos, however, induces possibly permanent paralysis, and seems to have affected at least a dozen employees of the Velsicol plant in Texas that manufactures it. [71a]

Another potential direct threat to human health posed by pesticides involves the possible teratogenicity, mutagenicity, or carcinogenicity of herbicides such as 2,4-D, 2,4,5-T, picloram, and cacodylic acid. Some of the toxicity reported in early studies of 2,4,5-T was due to contamination of the herbicide with the exceedingly toxic chlorinated hydrocarbon, dioxin. [72] The degree of risk to people posed by uncontaminated herbicides is in dispute, [73] but in view of the enormous increase in the use of these chemicals, caution is indicated.

For both chlorinated hydrocarbons and herbicides, the direct threat to humanity, as noted above, is difficult to assess. At present, however, it would appear that, as alarming as the direct threat may be, the *indirect threat* is much more serious. These compounds have the potential for irreversibly damaging the capacity of ecological systems to supply those essential services without which civilization cannot persist (Chapter 11).

TRACE METALS

A variety of trace metals are naturally present in the biosphere at low concentrations, cycling through atmosphere, surface water, soil, living creatures, oceans, and sediments in much the same ways as the nutrients discussed in Chapter 3. The same metals exist in ore deposits and in technological society in much greater concentrations, but in the context of the behavior of their dispersed forms in the biosphere they are called trace metals. Some are themselves micronutrients; some are toxic to people even at environmental concentrations that occur naturally; others have had their natural concentrations augmented by human activities to levels at which they become harmful. Among the trace metals of greatest health interest are lead, mercury, cadmium, arsenic, beryllium, nickel, chromium, selenium, vanadium, molybdenum, copper, and zinc. [74]

All of these metals are mined for industrial applications. Part of what is mined reaches the biosphere in the form of losses at various stages of processing; some

reaches the biosphere as the result of wear during the use of manufactured products; some gets there through disposal of worn-out products. Some of the metals are used in forms in which dispersal in the biosphere is intentional -- for example, drugs, gasoline additives, and agricultural chemicals. Virtually all of the metals tested above are present as contaminants in fossil fuels, particularly coal and petroleum; combustion of these fuels releases substantial quantities of the trace metals to the biosphere, either as particulates in the exhaust gases or in ash that is later incorporated into soil and surface water. [75] Even such human activities as cultivation and deforestation, which disrupt large areas of Earth's surface, may increase the rates at which trace metals are mobilized by outgassing and leaching.

Although it is sometimes mistakenly asserted that the contribution of human activities to producing the concentrations of trace metals found in the biosphere has been minor compared to that of natural processes, accumulating evidence on the global geochemistry of these elements leads to the opposite conclusion. [76] Table 10-9 shows the rates of mobilization by mining, emission to the atmosphere by human activities, estimated rainout from an unpolluted (prehuman) atmosphere, and natural flux to the oceans in rivers. The artificial flows approach or exceed the natural ones in almost every case.

The physical pathways and chemical transformations that govern the details of trace-metal hazards to people are complex and often ill-undentood. [77] Some chemical and physical forms of a given element are much more toxic than others (e.g., the methyl-mercury complex, CH^3Hg--, compared to metallic mercury); chemical transformations occur in both directions both with and without mediation of organisms; and low environmental concentrations can be turned into high ones by food chains. Some concentration factors in marine organisms are shown in Table 10-10.

The toxicity of trace metals to humans is generally clear at high concentrations and less obvious at low ones. The levels known to be dangerous vary widely; lead and cadmium are toxic at the same concentrations at which iron and zinc are beneficial, for example. Kinds of effects also vary: lead and methyl mercury damage the central nervous system; cadmium, arsenic, and selenium are known to be carcinogenic in animals, and the first two are directly toxic in other ways; beryllium is both carcinogenic and poisonous. [78]

In the following subsections we look more closely at lead, mercury, and cadmium as illustrative and relatively well-studied examples of the hazards of trace metals.

Lead

The effects of ingestion of lead in large quantities are well known. Symptoms of lead poisoning include loss of appetite, weakness, awkwardness, apathy, and miscarriage; it causes lesions of the neuromuscular system, circulatory system, brain, and gastrointestinal tract. [79] The most serious causes of acute lead poisoning in the United States today are the ingestion of chips of leadbased paint by small children and the contaminated moonshine whiskey made in lead-soldered automobile radiators. Painters, foundry and smelter workers, and typographers risk acute lead poisoning occupationally.

Overexposure to lead may have been a factor in the decline of both the Greek and Roman civilizations. [80] The Romans lined their bronze cooking, eating, and wine-storage vessels with lead. They thus avoided the characteristic unpleasant taste of copper and the obvious symptoms of copper poisoning, trading them for the pleasant flavor of lead and the more subtle symptoms of lead poisoning. Even in more recent times, lead poisoning due to drinking acidic beverages from pewter mugs was not uncommon ("modern" pewter no longer contains lead).

Contemporary industrial societies have largely eliminated the lead-lined pipes and vessels that probably made acute lead poisoning rather common in earlier times. On the other hand, contemporary industrial activities are mobilizing and dispersing far larger quantities of lead on a global scale than previously was the case, and the fate of this lead in the environment and the possibility of chronic insults to human health as a result have become topics of legitimate concern.

The quantity of lead mined worldwide in the early 1970s was around 3 million metric tons annually, about 10 times more than is mobilized annually by the natural weathering of crustal rocks. [81] The largest single use of the lead that is mined is in storage batteries, followed by

fabricated items such as shotgun pellets, bullets, radiation shields, and lead weights. Somewhat more than 10 percent of the lead mined was being used in the early 1970s as a gasoline additive in the form of tetraethyl lead, a compound considerably more mobile in the biosphere and perhaps three times more toxic than elemental lead. [82]

Emissions of tetraethyl lead to the atmosphere around 1970 were estimated at 400,000 metric tons annually; the amount added by combustion of coal and oil containing lead as a trace contaminant was about 100 times smaller. [83]

The pattern of increase in the lead contamination of the atmosphere has been revealed by studies of the lead content of the Greenland ice cap. The ice cap "lead load" increased about fivefold between 1750 and 1940, and twentyfold between 1750 and 1967. By comparison, studies show that the content of sea salts in the Greenland ice cap have not changed since 1750, indicating that changes in the overall pattern of deposition of materials in the ice is not the cause of the lead increase. [84] That similar patterns of lead contamination are not found in the Antarctic ice cap lends strong support to the thesis that atmospheric lead pollution originated first with lead smelting and then more recently with the combustion of gasoline, two sources of contamination that are concentrated in the Northern Hemisphere. The spread of pollution to the Southern Hemisphere is largely blocked by the hemispheric restriction of atmospheric circulation patterns (see Chapter 2).

Another indication of the scale of civilization's impact on environmental lead concentrations is that the lead content of the open ocean has increased threefold to fivefold since the introduction of lead-based gasoline additives. [85] Lead is the only heavy metal whose openocean concentrations had been measurably influenced by civilization as of the early 1970s.

Table 10-11 shows lead concentrations that have been measured in various parts of the human environment, together with "permissible" standards for air and drinking water set by agencies in the United States. The numbers in the table suggest -- and research has confirmed -- that plants do not readily take up metallic lead from the soil, but they extract tetraethyl lead (probably directly from the air as well as soil) much more efficiently. [86] The latter concentration effect is one of the factors that now make ingestion of lead in the diet a more significant pathway for human exposure than breathing of it.

How much lead are residents of the United States getting and what are the consequences? The average intake of lead in the American diet is 0.3 to 0.4 milligrams per day, of which less than 10 percent is absorbed and the remainder promptly excreted. [87] This intake is about 20 times larger than that to be expected in a natural environment (i.e., one uncontaminated by industrial activities). Intake from breathing urban air typically is in the range of 0.02 milligrams per day, but the fraction absorbed is perhaps 40 percent. The typical body burden of lead in industrial countries is roughly 100 times the natural figure.

Typical human exposures to lead in industrial society, then, are far higher than exposure in an uncontaminated environment. On the other hand, they are lower by factors of 3 to 10 than exposures that have been associated with obvious symptoms of severe lead poisoning. A vigorous controversy rages about whether lead intake at the levels now being experienced by the large populations of urban regions are actually damaging to health.

It is known that lead interferes with the production or operation of a variety of enzymes that play important roles in the human body. Changes in enzyme levels are detectable when blood levels

of lead reach 30 micrograms per 100 milliliters of whole blood (0.3 ppm -- parts per million); typical blood levels in urban environments are 0.1 to 0.2 ppm and individuals occupationally exposed to heavy automobile traffic often exceed 0.3 ppm. [88] Clinical symptoms of lead poisoning first appear at blood levels of 0.5 ppm in children and 0.8 ppm in adults, and some observers consider the demonstrated interference with enzymes below these levels inconclusive as evidence of real harm. [89] Experiments have demonstrated impairment of learning in lambs produced by ewes with lead levels in blood of 0.34 ppm, however, and correlations of hyperactivity and mental retardation with blood levels in children suggest that 0.25 ppm may already represent the danger level. [90] It is possible, of course, that high lead levels in blood are coexisting symptoms of certain physiological disturbances, rather than the causes of these, but it seems imprudent to assume this without real evidence. If the pessimists are correct, there is no margin of safety between harmful levels of lead and those experienced by many members of urban populations.

Neurological effects of lead are discussed at length in D. Bruce-Smith and H. A. Waldron, "Lead, behavior, and criminality".

Ironically, the most significant steps taken in recent years to reduce the amount of lead in the human environment have been motivated not by concern about lead's toxicity but rather by laws restricting emissions of other pollutants. Specifically, the catalytic converters used by most American automobile manufacturers to meet the emissions standards mandated by the Clean Air Act of 1970 for hydrocarbons, carbon monoxide, and nitrogen oxides are fouled and rendered inoperative by the tetraethyl lead in gasoline. As a result, the Environmental Protection Agency in late 1973 promulgated a schedule for the reduction of the lead content of gasoline and required all retailers above a specified volume of business to make available a lead-free gasoline after July 1, 1974. [91] Before these regulations went into effect, the lead content in gasoline actually had been rising somewhat, from 2.3 grams of lead per gallon in 1963 to 2.6 grams of lead per gallon in 1970. [92] The EPA schedule required that the average lead content of gasolines offered for sale not exceed 1.7 grams per gallon after January 1, 1975, and 0.5 grams per gallon after January 1, 1979. The latter figure was successfully challenged as being "without scientific basis," in a lawsuit brought by the Ethyl Corporation in 1974; the EPA has appealed. [93]

Mercury

Mercury is a heavy, silvery metal that is liquid at room temperature. It is used in the production of chlorine (which in turn is used in large quantities in the production of plastics) and of caustic soda (which has many industrial uses), as well as in the manufacture of electrical equipment. Smaller quantities are used in paints, agricultural fungicides, and dental amalgams, in the pulp and paper industry, in medicines (so-called mercurials), and in thermometers. World production of mercury in 1970 was about 10,000 metric tons, of which about 25 percent was used in the United States. [94]

A detailed study of the fate of commercial mercury in the United States around 1970 indicated that 76 percent was for applications where the mercury is recyclable in principle (e.g., chlorine-caustic soda manufacturing, electrical equipment) and 24 percent was for dissipative uses (e.g., paint, fungicides, phannaceuticals). [95] Losses to the environment in the *potentially* recyclable chlorine-caustic soda application amounted to 23 percent of the total U.S. mercury use, however. In total, then, at least half of the 2500 tons of mercury used annually in the United States reaches the biosphere in one form or another (sometimes, as with paints, after a long delay).

Other sources of mercury added to the environment by the activities of civilization are the roasting of sulfide ores of other metals (possibly contributing as much as 2000 metric tons of mercury per year worldwide [96]) and the combustion of fossil fuels containing mercury as a trace contaminant.

The mercury content of coal varies widely, with published values for different coals ranging from 0.01 ppm to 33 ppm by weight. [97] If the average value worldwide should be as high as 1 ppm, then mercury mobilized by coal combustion would be about 3000 metric tons annually. It was shown in tests on one large United States coal-fired power plant that more than 90 percent of the mercury in the coal goes up the stack and less than 10 percent remains in the bottom ash. [98] Other work has shown that the mercury and other trace-metal contaminants of coal are preferentially concentrated in the particles at the small end of the size-range produced by combustion; these particles are the most likely to escape stack-gas controls, the most persistent in the atmosphere, and the most likely to penetrate to the lungs upon inhalation. [99] Unfortunately, it cannot be assumed even that the mercury remaining in particles large enough to be collected by control devices or in bottom ash stays out of the environment; it is subject to outgassing and leaching from ash storage piles.

Tanner et al., "Mercury content of common foods determined by neutron activation analysis".

The mercury content of petroleum is even less wellmeasured than that of coal. It was found to be 10 ppm in one (probably exceptional) circumstance. [100] If it averages I ppm worldwide, the mercury entering the atmosphere as a result of oil combustion could be approximately 3000 metric tons.

By how much have the activities of civilization altered the natural flows of mercury through the environment? The prehuman rate of mercury mobilization by weathering has been estimated as about 1000 metric tons per year. [101] The precivilization flow of mercury from the surface to the atmosphere by outgassing from land and oceans was perhaps 25,000 metric tons per year. [102] A reasonable estimate would seem to be that civilization (as of 1970) has increased the amount of mercury that is flowing in rivers from land to oceans to about 4 times the natural value, and the flow of mercury from surface to atmosphere by roughly 50 percent. [103] (Possibly the increase of

natural outgassing by surface-modifying activities of civilization is as important as direct human inputs of mercury.) The uncertainty in these figures is large (at least a factor of 2 up or down) but they are consistent with a doubling in the mercury content of precipitation in the last several decades as suggested by ice samples from the Greeland ice sheet. [104]

Some concentrations of mercury that have been measured in various parts of the natural and "man-made" environment are summarized in Table 10-12. It is important, in pondering the significance of these levels, to distinguish between the different chemical forms in which mercury occurs. Inorganic mercury can be either the metallic form, encountered environmentally principally as the vapor, or any of a variety of inorganic salts and complexes in which the mercury has oxidation numbers of + 2 (mercuric compounds) or + 1 (mercurous compounds). Inorganic mercury compounds are toxic, but not extremely so, and they are not concentrated in food webs. The form most commonly encountered in the Earth's crust is insoluble mercuric sulfide (HgS), which under oxidizing conditions is converted to more soluble $HgSO_4$. Mercury compounds reaching Earth's surface generally degrade to the metallic form, which volatilizes under the action of sunlight. [105]

Organic mercury occurs most commonly as phenyl mercury ($C_6H_5H_g+$), methyl mercury (CH3Hg+), and methoxyethyl mercury ($CH_3OCH_2CH_2Hg+$), the first form in paints and pulp and paper operations, and the latter two forms in agricultural chemicals. These forms are much more toxic than inorganic mercury, and are concentrated in food webs. It was discovered in 1969 that microorganisms widespread in sediments are capable of forming methyl mercury and dimethyl mercury from inorganic mercury compounds. [106] It is this phenomenon that has made mercury poisoning from high levels of methyl mercury in fish so serious a threat.

The symptoms of chronic poisoning by inorganic mercury have been known for a long time. They include headache, fatigue, irritability, tremors, and other nervous

[105] Wallace et al., *Mercury*.
[106] Ibid.

disorders. Chronic mercury poisoning from the processing of felt used for hats was the origin of the phrase "mad as a hatter." [107] A U.S. standard based on early experience in the felt-hat and electronics industries allows 100 micrograms of inorganic mercury per cubic meter of air for an eight-hour working day; an international symposium has suggested a value half as high for the elemental form; and studies of animals exposed continuously to mercury vapor have led the Russians to establish a 24-hour limit of 0.3 micrograms per cubic meter. [108] (One microgram per

cubic meter is roughly I part per billion by weight.) There is some evidence of mercury poisoning among people occupationally exposed to mercury vapor at 10 to 30 micrograms per cubic meter. [109] About three-quarters of any metallic mercury vapor inhaled is absorbed, and once in the body, inorganic mercury concentrates preferentially in the kidney, liver, and brain. [110] A tentative standard for mercury in drinking water has been set by the U.S. Public Health Service at 5 parts per billion. [111]

Among organic forms of mercury, phenyl mercury is converted rapidly in the body to inorganic forms and is not considered more dangerous than these. Methyl and ethyl mercury (often termed alkyl mercury compounds) are similar to each other and much more dangerous than the phenyl and inorganic forms. [112] Methyl mercury concentrates in the body in red blood cells and in the nervous system, and it selectively attacks nerve cells. Its biological half-life in human beings is about 70 days. [113] Symptoms of methyl mercury poisoning may first appear weeks to months after exposure to toxic concentrations; they include "numbness and tingling of the lips or hands and feet, ataxia (lack of motor coordination), disturbances of speech, concentric constriction of the visual fields, impairment of hearing, and emotional disturbances." [114] This type of poisoning is sometimes called Minimata disease, because the first recorded epidemic of the sort occurred in the Minimata district of Japan (Box 10-4). Cases of fatal poisoning from ingestion of grain treated with organic mercurial fungicides have been documented in Iraq, Pakistan, Guatemala, and the United States. [115]

The United States standard for airborne organic mercury compounds is 10 micrograms of Hg per cubic meter, or 10 times less than the inorganic standard. Breathing this concentration for an eight-hour work day (10 ml of air inhaled) would produce a daily intake of 100 micrograms of Hg, an average blood concentration of 60 micrograms of Hg per liter of whole blood (60 ppb), and a brain concentration of 1,000 ppb. [116] The blood level at which chromosome damage has been observed is about 200 ppb, overt symptoms of mercury poisoning occur between 400 and 1,000 ppb Hg in blood, and the blood level associated with inevitable injury and death is variously stated as 1000 to 1400 ppb. [117]

The United States Food and Drug Administration standard for methyl mercury in fish is 500 ppb Hg on a wet-weight basis. To receive a daily intake of methyl mercury equal to that permitted by the occupational air standard (100 micrograms per day) would require the consumption of only 200 grams of fish per day (a bit under half a pound) contaminated to the 500 ppb permitted by the standard. Blood levels of methyl mercury corresponding to chromosome damage could be reached by consuming about 600 grams of fish per day contaminated at this level; such heavy fish consumption is most unusual in the U.S. diet. In the early 1970s, there were fishing restrictions in force in the U.S. in 18 states because of mercury contamination. [118] The recovery time for contaminated waters is very slow, ranging from tens to perhaps hundreds of years. [119]

Cadmium

Cadmium is physically and chemically similar to zinc, and the two metals always occur together in nature. Whereas zinc is essential to life, however, cadmium is

BOX 10-4 The Minimata Incident

In Minimata, Japan, a small city on the west coast of Kyushu, the economy is dominated by the chemical plants of Chisso Corporation. * Pollution problems affecting local fishermen have been occurring for half a century, but the problem that was to make Minimata world famous first showed up in the early 1950s. In 1953, "Birds seemed to be losing their sense of coordination, often falling from their perches or flying into buildings and trees. Cats, too, were acting oddly. They walked with a strange rolling gait, frequently stumbling over their own legs. Many suddenly went mad, running in circles and foaming at the mouth until they fell -- or were thrown -- into the sea and drowned." ** This "disease of the dancing cats," as it was known to the local fishermen, soon spread to fishermen and their families, with horrifying results. Severe trembling and mental confusion were followed by numbness, disturbed vision and speech, general loss of control of bodily functions, violent thrashing unconsciousness, and, in some 40 percent of the victims, death. By July 1970, the number of officially recognized cases had climbed to 121, with 46 deaths -- and only the more severe cases are officially recognized. †

Although Chisso Corporation (with some governmental cooperation) did everything possible to prevent the blame from being laid at its door, by 1959 an independent study had shown that Minimata disease was methyl mercury poisoning and that Chisso's effluents were the "likely source." Soon thereafter Chisso offered minimal compensation, the start of a long battle for financial aid for victims at Minimata and other sufferers of methyl mercury poisoning who began to appear at Niigata on western Honshu in the mid-1960s. ‡ It was not until 1968 that the government of Japan recognized officially that mercury was the cause of Minimata disease, and not until 1973 that Chisso finally was forced to admit its culpability and to agree to pay reasonable compensation. By 1975, careful health surveys had resulted in the uncovering of some 3500 victims of Minimata disease, and an estimated 10,000 additional people may still develop symptoms. Chisso, meanwhile, is in financial trouble because of the costs of indemnifying victims and has resorted to financial stratagems to avoid payment -- including spinning off profitable subsidiaries to open the possibility of Chisso itself declaring bankruptcy.

inimical to life. Even in small quantities it causes kidney dysfunction and bone demineralization, the latter especially if combined with a calcium deficiency. If inhaled, it causes fibrosis of the lungs and probably emphysema, and there is some evidence from animal studies that it may be teratogenic and carcinogenic. [120]

World production of cadmium in the early 1970s was around 17,000 metric tons annually. [121] The principal uses were electroplating, in stabilizers for plastics, and in pigments, alloys, and batteries; most of these uses are dissipative and nonrecyclable. A significant amount may reach the atmosphere through smelting and reclamation of steel scrap and incineration of plastics. The content of cadmium in fossil fuels is not well established, but a modest number of measurements indicate that it may be around 0.5 ppm in oil and may average 1 ppm in coal. Were this the case, emissions to the global environment from burning fossil fuels would be in the range of 5,000 metric tons per year. The natural rate of flow for cadmium through the environment as a result of weathering has been estimated, from oceanic sedimentation rates, at 500 metric tons per year. [122] The flow from mining alone is more than 30 times larger. Cadmium provides one of the most impressive examples of a human perturbation dwarfing the "natural background."

The principal human intake of cadmium among nonsmokers in relatively unpolluted areas appears to be in food; 20 to 50 micrograms per day is ingested and, of

this, perhaps 2 micrograms is retained. Smokers may absorb 0.2 micrograms per cigarette, making a pack per day equivalent to twice the absorption in the diet. An intake of 5 parts per million cadmium in air for 8 hours delivers a lethal dose, and 1 part per million for 8 hours is dangerous. The recommended Threshold Limit Value (recommended not to be exceeded in work environments) in the United States is 100 parts per billion (0.1 ppm), although it is unlikely that this level is harmless. Part of the cadmium problem is that the fraction not excreted immediately has an exceedingly long half-life in the body--around several hundred days--so that low doses received over a long period can lead to accumulation of a high body-burden. The U.S. drinking water standard for cadmium is 10 parts per billion, a level that is not infrequently exceeded.

Major toxic effects due to cadmium poisoning have been documented in industrial workers and in villages in Japan whose water supply was contaminated with drainage from a cadmium mine. Acute cadmium poisoning received the name Itai-Itai or "ouch-ouch" disease in Japan, because

of the painfulness of the associated bone and muscle abnormalities. Effects on people at lower dose rates are still undocumented, but are suspected.

There is every reason to believe that cadmium is accumulating steadily in the environment, and its known characteristics as a persistent cumulative poison in the body give much reason for concern. [123]

FLUORIDES

Fluoridation of public water supplies for partial protection against tooth decay is an emotion-charged subject. The scientific evidence supporting the efficacy and safety of mass fluoridation at the generally recommended level of 1 milligram per liter of water (1 ppm) is not as good as it ought to be, but neither is there convincing evidence that it is harmful. [124] Although there are certainly some cranks in the antifluoridation school, there are also some serious and competent scientists and responsible laymen who have been unmercifully abused because of the position they have taken on this controversial issue. Perhaps the strongest argument against mass fluoridation of drinking water is that individual treatment with fluoride is simple and can be supplied cheaply on public funds for those wishing to use it.

There is no question that fluoride is toxic in high concentrations, and fluoride pollution from a variety of industrial activities is a significant problem. Fluorides are discharged into the air from steel, aluminum, phosphate, pottery, glass, and brick works. These sources together emit perhaps 150,000 tons of hydrogen fluoride annually, and the same activities emit some tens of thousands of tons of fluorides annually into waterways. [125] Intentional addition of fluorides in fluoridation programs makes a modest but not negligible contribution of perhaps 20,000 tons per year to the human-caused fluoride inputs to the environment.

The main problems encountered in trying to evaluate health threats from fluoride pollution are familiar ones: the boundary between safe and unsafe levels is a fuzzy one; some individuals are more sensitive than others; and fluorides may act in combination with other pollutants to do damage at concentrations where the fluorides alone would not be harmful.

Fluorides have been shown to concentrate in food chains, and evidence suggesting a potential for significant ecological effects is accumulating. [126] Harm to terrestrial plants and algae at concentrations encountered in polluted environments has been documented, and the ability of certain plants and microorganisms to synthesize particularly toxic organic fluorides has been demonstrated. The toxicity of inorganic and organic fluorides to soil organisms is essentially unexplored and is a potential danger point.

CHEMICAL MUTAGENS

Many chemicals found in the environment are considered hazardous because they, like ionizing radiation (discussed in the following section), are able to cause

---

[126]Ibid.

mutations. Mutations are sudden, inheritable changes in the makeup or arrangement of the genetic information that is coded into the structure of giant molecules of deoxyribonucleic acid (DNA). [127] These changes in the genes are important to us for two basic reasons--because they affect the genetic composition of future generations and because they appear to be involved in the production of cancers (carcinogenesis is discussed below).

Individual mutations are thought to be random events, so that one cannot specify which gene or genes will be affected when an organism is exposed to a *mutagen* (mutation-causing agent). Similarly, when a mutation is detected, it is ordinarily impossible to identify the mutagenic agent. Mutations are also rare events--in most animals (including *Homo sapiens*) an average rate would be around 1 mutation per 1 million genes per generation--the rate varying from gene to gene. [128] Mutations are an important source of the variability that is essential to the evolutionary process. It is generally agreed by evolutionists, however, that spontaneous mutation rates and other evolutionary properties of human populations provide more than sufficient genetic variability to allow humanity to evolve in response to current or foreseeable selection pressures. Spontaneous mutations are those that occur naturally. About 10 percent of them are thought to be caused by "background" radiation (see following text), and the remainder by unavoidable errors in the cells' manipulations of the genetic information and by unknown chemical mutagens. [129]

Mutations may be thought of as small, random changes in an extremely complex mechanism. It is not surprising, then, that most of them are harmful to an organism--or, in the jargon of the geneticist, *deleterious*. The chance of a mutation's being beneficial is small, for the same kind of reason that a random change in the circuitry of a TV set or computer is unlikely to improve its functioning. Deleterious mutations--which means 95 percent or more of *all* mutations--are normally weeded out of the gene pool of a population by natural selection (Chapter 4). In human populations, however, medical advances have made it possible for individuals carrying deleterious mutations to survive and breed, thus limiting the action of selection. For example, some human groups may be accumulating deleterious mutants that cause nearsightedeness or farsightedness because widespread use of eyeglasses has lessened the selective pressures against such genes. [130] For this reason many geneticists are concerned about long-term deterioration of the quality of the human gene pool and a corresponding decrease in the quality of life. [131] Even though, for example, nearsighted people and certain diabetics may be perfectly viable in the environment of a highly technological society today, and people carrying genetic defects such as that which causes Tay-Sachs disease may be made normal in an environment of the future, increase in the genes associated with these disorders is not to be taken lightly. Treatment of such genetic disorders involves a social cost, and one that future societies might be unwilling or unable to bear.

There is every reason, then, to avoid increasing the human mutation rate by the exposure of people to man-made chemical mutagens. The first problem in so doing is to determine which of the hundreds of thousands of synthetic chemicals released into the environment are mutagenic. The problems of screening chemicals for mutagenicity (mutagenetic activity) are numerous. [132] The test system must be very sensitive to detect a rare mutation with a small effect, and the results of the test must be highly reproducible. The test must be able to

---

[127] *Deoxyribonucleic acid* is the repository of genetic information in the cells of all higher organisms (in a few viruses a very similar compound, RNA, is used). These are giant molecules (macromolecules) made up of two long sequences of subunits called nucleotides. Four kinds of nucleotides are found in DNA, each having a different nitrogenous base that can pair with just one of the other bases. The base pairs hold the long sequences together like the rungs of a long, twisted ladder--the famed double helix. The genetic information is coded into the sequence of the base pair "rungs." For a simple review of the biochemical basis of heredity, see P. R. Ehrlich, R. W. Holm, and I. Brown, *Biology and society*. A biochemical explanation of kinds of mutations can be found in J. D. Watson , *Molecular biology of the gene*, 3d ed. Benjamin, New York, 1976, or any other modern text in biochemical genetics.

[128] Technically the rate is given per locus. For further general discussion of mutation and its evolutionary significance, see P. R. Ehrlich, R. W. Holm and D. R. Parnell, *The process of evolution*, especially chapter 3 and in particular the section on chromosomal alterations, which we have included here under "mutations." A comprehensive discussion of mutation in human populations may be found in L. L. Cavalli-Sforza and W. F. Bodmer , *The genetics of human populations*.

Blood or bone marrow cell genetics	1 to 5 weeks	Moderate	Moderate		Potentially
Specific gene mutations	2 to 3 months	High to very high	High to very high	Unknown	

*Operating costs vary widely, depending upon the exact procedure and the number of substances tested simultaneously. Very low is approximately $1000;
low is $1000 to $5000; moderate is $3000 to $10,000; high is $10,000 to $20,000; and very high is $25,000 upward.

**Since most of these test systems do not detect all classes of gene mutation or chromosomal alterations, these columns refer only to the detectable effects.

Source: Data from Council of the Environmental Mutagen Society, Committee on Environmental Mutagenic Hazards.

detect the variety of biochemical and microstructural events that are lumped under the rubric *mutation*. (A microstructural event is a change in chromosome [133] structure or number.)

The test system should have metabolic properties similar to those found in human beings. Many examples are known of chemicals that are not mutagenic until they are altered into another chemical form by the life processes of an organism. Similarly, various mutagens have been shown to be promptly metabolized into inactive forms in some organisms so that they cannot cause mutations in them. An ideal test system would, then, perfectly simulate our life processes. Related to this problem is that of the interaction of mutagens. Two substances may interact so that the mutagenicity of one of them is enhanced. For example caffeine, which inhibits DNA repair processes, may increase the rate of mutation-induction by various mutagens.

A variety of mutagen screening systems have been developed. These include bacterial systems that can detect biochemical mutations but not microstructural alterations (in chromosomes), and systems using fungi, higher organisms or mammalian cells in cell culture, that can detect both mutations and some chromosomal changes.

The properties of a variety of these systems are shown in Table 10-13. With the exception of the plant systems and *Drosophila*, the nonmammalian test systems shown include an activation system so that inactive compounds may be converted to mutagens if that would occur in a mammal. (*Drosophila* possesses at least one enzyme system that activates some mutagens in a manner similar to a system found in the liver of mammals.) One procedure for activation involves the addition of metabolically functional mammalian tissue extracts to the test system along with the suspected mutagen. In a second activation procedure an intact mammal (either *Homo sapiens* or a rodent) is exposed to the suspected mutagen and tissue extracts from the mammal are added to the test system. In a so-called host-mediated assay the microorganisms or mammalian cells used in the test system are introduced into the body cavity of a rodent, which is then

---

[133] Chromosomes are the organelles (tiny organs) of the cell nucleus, with which most of the nuclear DNA is associated.

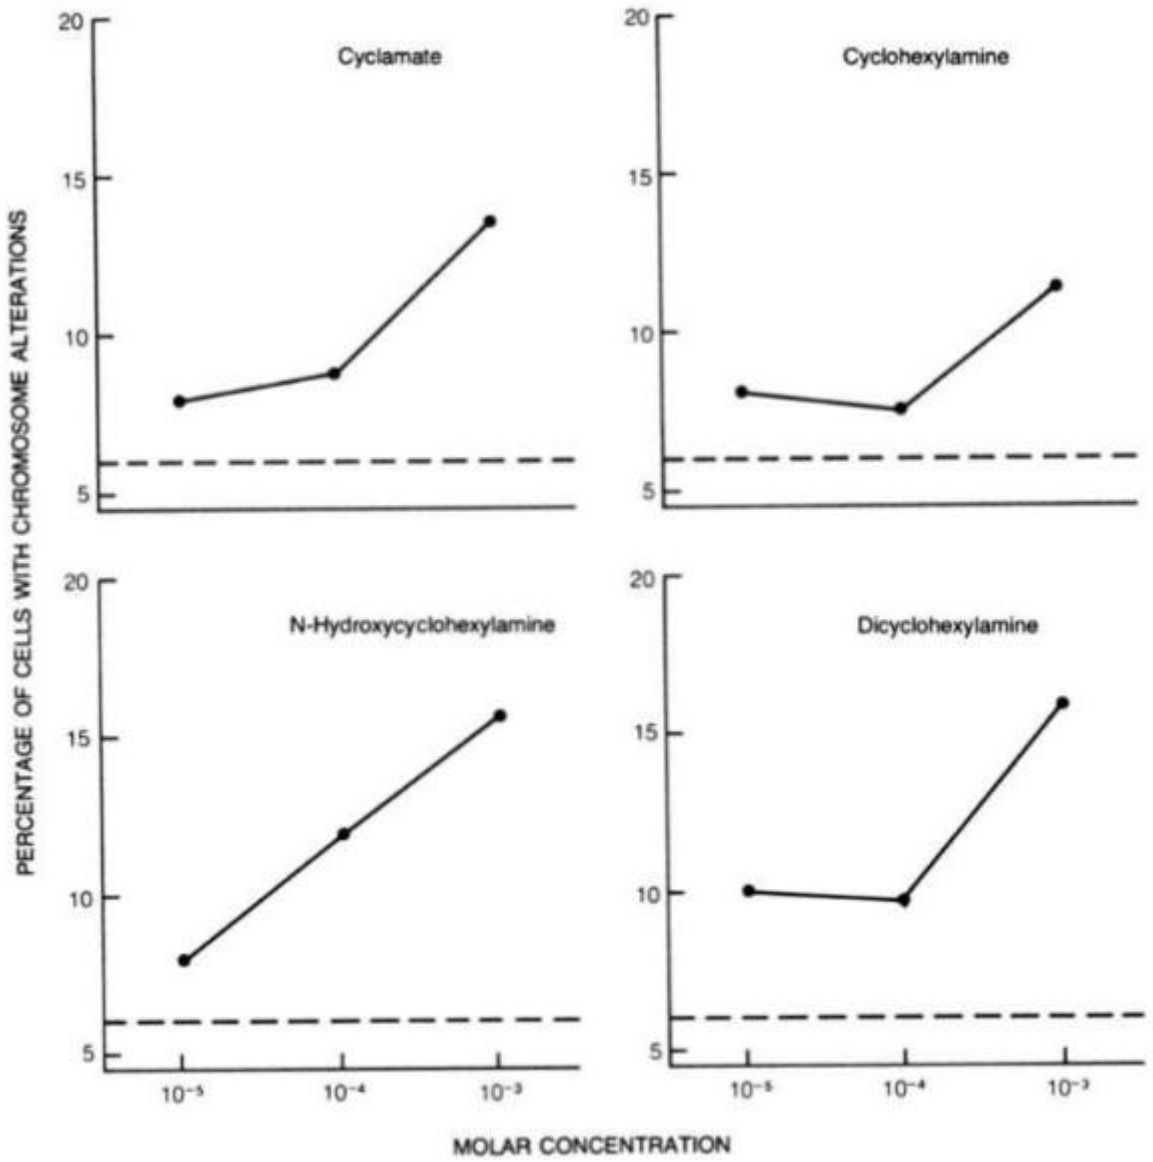

FIGURE 10-5 Chromosomal alterations in tissuecultured human white blood cells as a function of doses of a cyclamate and three related chemicals. Exposure was for 25 hours. Concentrations are given in moles per liter (a mole is the weight in grams of a compound numerically equal to its molecular weight). Each point represents analysis of 100 cells. (Data from Stoltz et al., 1970.)

TABLE 10-14 A Sample of Mutagens

Mutagen	Use or occurrence
Acridine orange	Dye
Aflatoxin	Fungal toxin which may contaminate foods
Benzidine	Manufacture of dyes
Benzo[a]pyrene	Air pollution resulting from incomplete combustion
Captan	Agricultural fungicide; antibacterial agent in soaps
Chloramphenicol	Antibiotic
Cigarette smoke concentrate	Smokers' lungs

Mutagen	Use or occurrence
Cyclamate	Artificial sweetener
Dichlorvos (vapona)	Shell No-Pest Strip insecticide
Ethidium bromide	By veterinarians: against trypanosomal infections of cattle
N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)	Industrial alkylating agent
Proflavine	Antiseptic
Sodium nitrite	Many industrial, medical, and veterinary uses
Trimethyl phosphate (TMP)	Gasoline additive, flame retardant, solvent for paints, catalyst for preparation of plastic materials
Uracil mustard	Anticancer drug
Vinyl chloride	Manufacture of plastics; as refrigerant, aerosol propellant

exposed to the suspected mutagen. The test microbes or cells are later recovered and checked for mutations.

The results of one series of mutagenicity tests using cultures of human white blood cells are shown in Figure 10-5. The four suspected mutagens tested were: cyclamate, an artificial sweetener; cyclohexylamine and Nhydroxycyclohexylamine, both breakdown products of cyclamate; and dicyclohexylamine sulfate, an occasional contaminant of cyclamate. As can be seen in the figure, a 25-hour exposure to high concentration of any of these compounds caused a rise in the percentage of cells in the test culture with chromosonul alterations. [134]

An enormous number of compounds have already been reported to be mutagenic in one or more test systems (Table 10-14). They include pesticides, dyes, refrigerants, anticancer drugs, drugs used in veterinary medicine, air pollutants, fuel additives, tranquilizers, chemicals used in the plastics industry, antibiotics, and a variety of industrial akylating agents (chemicals used in industrial processes to introduce alkyl--that is, ethyl, propyl, and such--radicals into organic molecules). [135]

Identifying a chemical as a mutagen is, however, only the first step in evaluating the hazard it poses. One must also know, among other things, if the test results can properly be extrapolated from the test system to Homo sapiens, what patterns of susceptibility there will be in the human population, how much of the chemical is loose in the environment and how it is distributed, the current and projected levels of production, and the persistence of the compound. All these factors must be integrated into a difficult cost-benefit analysis for which, at the moment, there are no

satisfactory guidelines. The basic problems are similar to those discussed below in the evaluation of the hazards of radiation. One can attempt to place a value on the total future cost of one individual's being exposed to a given dose (concentration multiplied by time) of a mutagen, just as attempts have been made to estimate the dollar cost of one person-rem of radiation exposure. [136] But the assumptions that must be made in order to do this border on the ludicrous.

The overall risk to humanity from mutagenic chemicals seems great, but for the reasons indicated above, difficult to evaluate. As the distinguished geneticist James F. Crow put it, "There is reason to fear that some chemicals may constitute as important a risk as radiation, possibly a more serious one . . . . To consider only radiation hazards may be to ignore the submerged part of the iceberg." [137] The wise course would seem to be to reduce public exposure immediately to suspected mutagens to the greatest possible extent, tolerating unavoidable exposure only where the benefits seem great. But doing this can be extremely difficult. The case of cyclamate is an instructive one. In August 1970, cyclamates were banned by the U.S. Food and Drug Administration after a long battle with commercial interests. The argument for allowing their use was that they were important to diabetics and also saved lives by helping prevent obesity. This was countered with arguments that cyclamate-sweetened products were not particularly effective in weight reduction. Suggestions that products sweetened with cyclamates could be dispensed only to those with medical need (by prescription) led to counterarguments that the volume of business would be insufficient to keep an adequate variety of products available. In the end we think the right decision was made, but the decision-making process was long and agonizing. [138]

When one considers that the diet of most people in developed countries contains thousands of synthetic colors, flavors, thickeners, preservatives, emulsifiers, antibiotics, pesticides, and contaminants from packages, many of which may be mutagenic (and carcinogenic), one can begin to appreciate the magnitude of the problem.

IONIZING RADIATION

The year 1896 marked the discovery of two kinds of penetrating radiation, different in origin, but subsequently recognized to be related in character. The first of the two radiations was man-made, produced by a cathode-ray tube (then a technological curiosity), and was named X-rays by its discoverer, Wilhelm Roentgen. A scant few months later, Henri Becquerel discovered penetrating radiation emanating spontaneously from a

[137] Chemical risk to future generations.
[138] See, for example, J. S. Turner, *The chemical feast; Time*, August 26, 1974, p. 67.

compound of uranium, a phenomenon shortly thereafter given the name "radioactivity" by Pierre and Marie Curie . [139]

X-rays were subsequently shown to be energetic electromagnetic waves produced when fast-moving electrons were decelerated in encountering a "target" material (hence the German term *Bremstrahlung*, meaning "braking radiation"). Early studies of radioactivity showed that its emissions were of three kinds, which were named *alpha*, *beta*, and *gamma* radiation. Later it was shown that alpha and beta radiation were actually energetic particles, and that gamma radiation consisted of electromagnetic waves identical in some cases to Xrays but in other cases even more energetic. All these emissions (and some others since discovered) are today characterized as *ionizing radiation*, because the particles or waves involved are energetic enough to break electrons loose from atoms they encounter.

Although the phenomenon was not discovered until 1876, and its ubiquity was not recognized for some time thereafter, humanity lives and has always lived in a virtual sea of ionizing radiation. It comes from naturally radioactive rocks in Earth's crust, from naturally occurring radioactive materials that circulate in the biosphere, and from cosmic rays arriving from space. These natural sources of ionizing radiation have been augmented in the twentieth century by various medical, military, and commercial uses of radioactive materials and X-rays.

The long history and universality of exposure to ionizing radiation does not mean that it is harmless. The ionizing property--the ejection of electrons from the outer shells of atoms--is the key to the harm. Such ionization can destroy a chemical bond, and if the bond destroyed is in a molecule crucial to the function of a living cell, then harm to the organism may result. Some cells are dispensable to an organism made up of billions of them, but there are points of special vulnerability: death of a few cells in a fetus at certain stages can produce congenital abnormalities; mutations in germ cells can produce genetic effects that manifest themselves only in future generations; and damage to the DNA in other cells can produce cancer. There is reason to believe that a burden of such effects is, and always has been, associated with natural ionizing radiation. Obviously, the size of this burden has not been such as to imperil the survival of the human race, but neither can it be supposed to be negligible.

Radioactivity and ionizing radiation have been intensely studied since their discovery eighty years ago. Indeed, the often-heard statement that radioactivity is the most studied and best-understood major "pollutant" is almost certainly true. This is not to say, however, that understanding is adequate; it may be *less inadequate* than for other pollutants, such as heavy metals or nitrogen oxides, but many important uncertainties about ionizing radiation and specific radioactive materials remain unresolved. We treat some of them in the discussion that follows. Suffice it to say here that it would be foolish to view with complacency the significant additions to natural radiation exposure that contemporary civilization has already produced and any that it might contemplate producing in the future.

Properties and Pathways

The physical characteristics of radioactive transformations and the associated terminology are summarized in Box 8-4. Here we discuss the characteristics of different forms of ionizing radiation and how these characteristics affect the pathways that govern human exposure.

Particulate forms of ionizing radiation (alpha particles, beta particles, and neutrons) penetrate matter to distances that depend in part on their energies. Alpha particles consist of two neutrons and two protons, and thus are relatively massive. They travel only a short distance in air and generally cannot penetrate the dead protective layer of human skin. An alpha particle must have an energy of 7.5 million electron volts (MeV) to penetrate this layer, and few radioactive substances emit such energetic alphas. Thus, isotopes that emit alpha particles and nothing else (plutonium-239 is such an isotope) generally are dangerous only if they have access to the inside of the body; then the alpha particle can deposit its energy in living tissue, and, indeed, the massive particle does great

[139]See, for example, Merrill Eisenbud, *Environmental radioactivity*.

damage over the short pathway where its energy is deposited. Alpha particles are called high-LET (for high linear energy transfer) radiation because of this property.

Beta particles, being electrons or positrons and hence very light, are more penetrating than alpha particles of the same energy. The range of a negative beta particle in air is about four meters for every MeV of energy it starts out with; typical energies of beta particles are between a few hundredths of an MeV and a few MeV. To penetrate the dead protective layer of skin, a beta particle needs 0.07 MeV. Beta particles from krypton-85 and strontium-90 have more than enough energy to do this, but beta particles from tritium (hydrogen-3) do not. [140] Thus, tritium is of significance only as an *internal emitter*--irradiating cells from within the body. Krypton-85, a noble gas, is not absorbed by the body to any appreciable extent and so is of significance mainly as an *external emitter*. Strontium-90 is important as both an external and internal emitter.

The most penetrating forms of ionizing radiation are neutrons and gamma rays. Relatively few radioactive isotopes emit neutrons, but neutrons are produced in abundance in nuclear fission and nuclear fusion. Reactors of both kinds must be heavily shielded with lead, steel, and concrete to protect operating personnel from the neutrons produced. Gamma rays undergo attenuation in matter according to an exponential law of the form $I = I0\ e\lambda x$, where I is intensity, I0 is the initial intensity, x is distance traversed, and A is a constant that depends on the material being penetrated and the energy of the gamma rays. [141] For gamma rays of energies commonly encountered, attenuation passing through building walls reduces exposures to people inside by 10 to 70 percent for homes, and 70 to 90 percent for large commercial buildings. [142]

In summary, alpha particles are dangerous only if emitted within the body; beta particles are most dangerous when emitted within the body, but energetic ones can penetrate several meters of air and the skin; and gamma rays and neutrons travel tens to hundreds of meters or more in air and can penetrate solid walls.

In addition to the type and energy of radiation emitted, radioactive substances can be distinguished according to their different radioactive half-lives (Box 8-3), their different behaviors in the physical environment, and their different behaviors in organisms.

A short half-life means that the amount of radioactivity declines rapidly. (Recall that radioactivity is measured in curies, where I curie equals 37 billion disintegrations per second.) If one starts with one curie of an isotope with a half-life of one minute (sodium-25 is such an isotope), it will have decayed to one trillionth (10-12) of a curie after only 40 minutes. An initial curie of an isotope with a long half-life, such as the 4.5 billion years of uranium-238, is still essentially a curie a million years later--its activity changes only imperceptibly in time periods that are short compared to the half-life.

Directly related to differences in half-life are large differences in *specific activity*--that is, the number of curies per gram of an isotope. One gram of iodine-131 (an isotope with a half-life of 8.05 days) represents 123,000 curies; but it takes over 6 kilograms of iodine129, with a half-life of 17 million years, to make a single curie. [143] A curie of strontium-89 (51-day half-life) would fit on the head of a pin; a curie of thorium-232 (14-billion-year half-life) weighs 10 tons.

Generally speaking, isotopes of intermediate half-life and specific activity are considered the most dangerous. Isotopes of very short half-life (minutes or less) decay away before they can move very far in the environment; those of very long half-life (millions of years or more) have such low specific activities that it takes large quantities to produce a high dose rate.

Summarized in Table 10-15 are the radiation types, half-lives, and specific activities of some of the most important natural and artificial radioactive isotopes.

The behavior of these isotopes in the environment varies widely with their chemical properties. Tritium is a

[140]For energies of the radioactive emissions of all known isotopes, see R. C. Weat, ed., *Handbook of chemistry and physics*.

[141]For values for common materials over the range of energies encountered, see U.S. Department of Health, Education and Welfare, *Radiological health handbook*.

[142]U.S. Nuclear Regulatory Commission, *Reactor Safety Study*, WASH-1400/NUREG-75-014, appendix 6, pp. 11-22.

[143]The formula relating specific activity to half-life is: curies/gram = 358,000/At $_{1/2}$, where A is the isotope's atomic weight and t $_{1/2}$ is the half-life in years.

TABLE 10-15
Physical Characteristics of Important Radioactive Isotopes

Name	Radiation*	Half-life**	Specific activity (Ci/gram)
Tritium	β-(0.02)	12y	9700
Carbon-14	β-(0.16)	5800y	4.6
Phosphorus-32	β-(1.7)	14d	2.8×10^{5}
Potassium-40	β-(1.3),γ(1.5)	1.3×10^{9}y	6.9×10^{-6}
Iron-59	β-(1.6)	45d	4.9×10^{4}

form of hydrogen: as hydrogen gas, it diffuses rapidly in the atmosphere; as a constituent of water, it follows the hydrologic cycle; it moves throughout living matter but does not concentrate along food chains or in particular organs. Strontium imitates calcium in nutrient cycles and organisms; it concentrates in bone and is called a "bone-seeker." Iodine concentrates in the thyroid gland; it reaches human beings very efficiently by the pathway: fallout on grass → cows → milk → people. Krypton is a noble gas and is not taken up appreciably by organisms; it diffuses throughout the atmosphere, from which it delivers an external dose to people and other organisms. Cesium is tightly bound to soil, staying near the surface and delivering an external dose of gamma radiation to passersby for years after being deposited; it also concentrates heavily in aquatic food chains. [144]

The biological half-life of an isotope refers to the time in which an organism excretes half of a given initial amount. Other things being equal, the longer the biological half-life of a radioactive isotope, the more dangerous it is; for the longer the material stays in the body, the more radioactive disintegrations take place. Tritium incorporated into the body in water is one of the more innocuous radioisotopes in this respect, being excreted with a biological half-life of around 10 days; strontium, in contrast, has a biological half-life in human beings of about 50 years.

Sources and Doses

Recall from Box 8-4 that the absorbed dose of radiation is measured in rads (where 1 rad means 100 ergs of energy deposited in each gram of absorbing material) or *rem* (where rem are obtained by multiplying rads by a *quality factor or Relative Biological Effectiveness*, which measures the efficiency of the energy in doing biological damage). Modest doses are usually measured in millirem (1 millirem = 10-3 rem).

Human doses from the natural background sources range in the United States from 100 to 250 millirem per year, with an average near 150 millirem per year. This

[144]See, for example, Eisenbud, *Environmental radioactivity*.

dose comes from cosmic rays [145] (40 to 160 millirem per year, increasing with elevation); from uranium and thorium and their decay chains, and from potassium-40 in Earth's crust (30 to 115 millirem per year, depending on location); from potassium-40 in food and water (17 millirem per year average); and from the decay products of radium--especially radon gas--in granite blocks and bricks (about 8 millirem per year average, with wide variations depending on building materials used). [146] These are the *whole-body doses*; doses to individual organs are higher in some instances.

The principal source of artificial radiation exposure is medical X-rays. A chest X-ray delivers about 9 millirem, a gastrointestinal tract X-ray about 200. The average medical and dental radiation exposure to members of the population of the United States is roughly 70 millirem per year, or about half the natural background. [147] A round-trip, cross-country airline flight adds about 4 millirem from extra cosmic radiation; fallout from nuclear-weapons tests worldwide delivers about 4 millirem per year (the figure was a few times higher at the peak of the testing in the early 1960s); and an hour per day of television viewing delivers about 0.15 millirem per year in the form of X-rays. [148] The average dose to members of the U.S. public from the nuclear-power industry around 1970 was 0.01 millirem per year. [149] Most of the exposure from nuclear operations was due to the routine release of tritium and krypton-85.

Health Impacts and Standards

High doses of radiation delivered within a short period of time can produce acute illness or death within hours to weeks after the exposure. Such doses, in the range of 100 rem (100,000 millirem) to 1000 rem or more, could be experienced by individuals near the detonation of a nuclear weapon, or in the pattern of most intense fallout from such a weapon, or by individuals downwind of a major accident at a nuclear reactor or fuel-reprocessing plant, or by workers in severe industrial accidents involving mishandling of radioactivity.

At whole-body doses of 100 to 200 rem, the effects are mainly vomiting, fatigue, temporary sterility in males, and likely aborting of pregnancies of less than two months' duration. At doses of more than 200 rem, some early deaths (in the first 60 days) occur in the more sensitive members of the population, and the $LD_{50/60}$ (dose killing 50 percent of the exposed persons within 60 days of exposure) is generally taken to be 250 to 450 rem. [150] One report has argued

that intensive medical care, including bone-marrow transplants, could increase the LD_{50} to 500 rem or more. [151] (The cause of death in the dose range below 1000 rem is infection and internal bleeding resulting from destruction of blood-forming cells in the bone marrow.) At doses above 1000 rem, death generally occurs within a week because of destruction of the lining of the gastrointestinal tract.

Delayed effects of large radiation exposures observed in survivors of the nuclear-bomb attacks on Japan in 1945 were most obvious among children who were *in utero* at the time of the explosion and were exposed to 10 to 150 rem; they suffered from a high incidence of microcephaly (small head circumference) and mental retardation. [152] The "emergency dose limit" promulgated by the International Council on Radiation Protection is 25 rem once in a lifetime. It is difficult to understand what operational significance this limit is intended to have.

The evidence is overwhelming that doses of radiation too small to produce the acute and early effects described above do produce a burden of extra cancers and genetic defects that is statistically predictable. The evidence on this point is of five kinds: (1) studies of the survivors of Hiroshima and Nagasaki; (2) studies of patients treated by radiation for nonmalignant diseases; (3) studies of

---

[145] Cosmic rays are mainly high energy protons and helium nuclei; these interact with nuclei in the atmosphere to form "secondary" particles and electromagnetic waves energetic enough to be ionizing radiation.

groups occupationally exposed to radiation, such as uranium miners and painters of radium dials on wrist watches; (4) studies of children whose mothers were X-rayed during pregnancy; (5) experimental studies on a wide variety of animals at varying doses and dose rates.

Induction of cancer in a population exposed to radiation is characterized by a latency period, during which no effect is evident, followed by a plateau period of elevated risk and then (for some cancers) a return to normal, spontaneous level of incidence. [153] For leukemia, the latency period may be as short as two years and the plateau of increased risk lasts about 25 years. For other cancers, the latency period may be 10 to 25 years, and studies of irradiated human populations have not yet revealed a termination of the plateau period.

The increase in cancer incidence due to radiation exposure is usually expressed as extra deaths per rem per million people exposed, or extra deaths per year per rem per million people exposed. The best estimate of the National Academy of Sciences 1972 review of these matters was an extra 200 cancer deaths (including those from leukemia) per million adults per rem. [154] This would represent an increase of about 2 percent in the "spontaneous" cancer rate. The percentage increase is much higher for children than for adults, and an important and, as yet, unresolved question is whether this *percentage* elevation of the cancer risk of an exposed child is maintained throughout life, as the spontaneous risk increases. The greatest sensitivity to development of cancer per unit of radiation dose is when the individual is exposed *in utero*.

Accounting for the age structure of the population, the NAS study estimated that increasing the background radiation exposure in the United States by 100 millirem per year would produce 3000 to 4000 additional cancer deaths per year and an equal number of nonfatal cancers. The uncertainty range given on their result spanned about a factor of 2, larger or smaller.

The assumption used by NAS and by all national and international standard-setting bodies is that the degree of elevation of risk of cancer is proportional to dose, down to the smallest doses and dose rates -- the *linear hypothesis*. Some authorities believe that low doses and dose rates are less effective than higher ones at inducing cancer and that the linear hypothesis therefore represents an upper boundary on consequences. [155] Other experts have put forward arguments to suggest that the linear hypothesis could *underestimate* the risk at low doses. [156] A very useful property of the linear hypothesis in estimating potential effects of radiation exposure is that the distribution of a given number of "person-rem" does not matter; that is, 1 million person-rem is expected to produce the same number of cancers, whether it is delivered as 1 rem to each of a million people, or as 10 rem to each of 100,000 people, or in any other combination adding up to 1 million person-rem (as long as individual doses do not exceed the 200-rem threshold for early effects).

Concerning genetic effects of radiation, there is again some controversy about whether the linear hypothesis gives the best estimate of expected effects. There is evidence of the existence of biological mechanisms that can repair some kinds of genetic damage, and one might conclude, therefore, that there is a dose-rate threshold, below which the repair mechanisms could "keep up." On the other hand, it is likely that the repair mechanisms are imperfect -- sometimes a "mistake" is made -- and animal experiments exposing large populations to low doses of radiation have not been able to demonstrate the existence of a threshold. The NAS review estimated that an increase of 100 millirem per year in average radiation exposure to the U.S. population would produce at equilibrium (assuming a steady 3.6 million births per year) between 600 and 15,000 additional serious genetic effects per year, compared to a "natural" total of about 200,000.

Standards for permissible radiation exposure have been set by the responsible national and international bodies at levels where it is supposed that the benefits from the activities producing the exposure outweigh the harm done by the exposure. Of course, no rigorous calculation of such a balance is possible, and none has been seriously attempted. The standards in widespread

use are 5 rem per year (whole-body) for workers over 18 years of age occupationally exposed to radiation (no occupational exposure is permitted under 18), 10 times less (500 millirem per year) to individual members of the public, and 170 millirem per year average to large populations. These limits are for artificial radiation exposure exclusive of medical radiation, an omission many experts would like to see remedied.

A controversy initiated in the early 1970s by John Gofman and Arthur Tamplin of the University of California and Lawrence Livermore Laboratory accelerated a trend in the direction of tighter guidelines. Not long after these scientists began urging a drastic tightening in the standards, based on estimates of the substantial number of extra cancers that would result if 170 millirem per year were actually received on the average in the United States, the U.S. Atomic Energy Commission proposed as a "design objective" that doses to persons in unrestricted areas (i.e., outside the plant boundary) be kept "as low as is reasonably achievable." It was made clear that this would be interpreted to mean 5 millirem per year whole-body dose from gaseous effluents and 3 millirem per year from liquid effluents in the case of commercial light-water reactors -- that is, a reduction of about 100-fold from previously accepted standards. The successor to the USAEC's regulatory responsibilities, the Nuclear Regulatory Commission, in 1975 adopted substantially similar design objectives for light-water reactors: 5 millirems to the whole body or to any organ from liquid effluents, 5 millirems to the whole body or 15 millirems to the skin from gaseous effluents. [157] In early 1977, the Environmental Protection Agency exercised its statutory authority to issue standards (which, unlike "design objectives," are unambiguously binding) applicable to *all* types of power reactors and other fuelcycle facilities (e.g., uranium mills, reprocessing plants). These standards restrict the dose to members of the public from any facility to 75 millirems per year to the thyroid gland and 25 millirems per year to any other organ or the whole body. [157a]

TABLE 10-16
Maximum Permissible Concentrations for Some Important Isotopes

Isotope	*Ci/m^3 in air*	*Ci/m^3 in water*
Tritium	2×10^{-7}	3×10^{-3}
Carbon-14	1×10^{-7}	8×10^{-4}
Krypton-85	3×10^{-7}	not applicable
Strontium-90	3×10^{-11}	3×10^{-7}
Iodine-131	1×10^{-10}	3×10^{-7}
Cesium-137	5×10^{-10}	2×10^{-5}
Radon-222	3×10^{-9}	not applicable
Radium-226	2×10^{-12}	3×10^{-8}

Isotope	*Ci/m³ in air*	*Ci/m³ in water*
Uranium-235	4×10^{-12}	3×10^{-5}
Uranium-238	3×10^{-12}	4×10^{-5}
Plutonium-239	6×10^{-14}	5×10^{-6}

Note: Figures are curies per cubic meter in air and water for public exposure. Where a distinction is made in the regulations between soluble and insoluble forms, the lower concentration is used here.

Source: U.S. General Services Administration, *Code of Federal Regulations*.

Maximum permissible concentrations (MPCS) of individual isotopes in air and water are published in the U.S. Code of Federal Regulations [158] for both occupational and public exposure. They have been based, for the most part, on an occupational dose of 5 rem per year and an individual public dose of 500 millirem per year. That is, the MPC for a given isotope in air in a nuclear-industry workplace is calculated so that a worker could not receive more than 5 rem per year from that isotope; the MPC for the same isotope in air breathed by the public would be smaller, both to account for full-time exposure and to produce the smaller maximum dose of 500 millirem per year. The MPCs account for the physical characteristics of the isotopes, including radioactive and biological half-lives and nature of the radiation, but not (in general) the possibility of concentration in food chains. Also, when more than one isotope is present at a time, as is usually the case, the concentrations must, of course, be kept below the single-isotope MPCs to keep the dose rate to the 5 rem per year or 500 millirem per year levels. The MPCs as of mid-1976 for some important isotopes are listed in Table 10-16. [159] The EPA's 1977 standards mean that nuclear power facilities will have to be operated in such a way that the average

[157]U.S. General Services Administration, *Code of Federal Regulations*, title 10, *Energy*, Part 50, Appendix I.

[157a]*Nuclear News*, EPA limits dose to public, releases from fuel cycle, February 1977, p. 30. The figures given are the limit for the sum of all exposure pathways: gases, liquids, particulates, and direct radiation.

[158]*Code of Federal Regulations*, title 10, part 20.

[159]Notice that to transform these standards to the mass basis generally used for conventional air and water pollutants--that is, micrograms per cubic meter in air or parts per million in water--one must apply the specific activity values in Table 10-15. For example, for tritium, 2 x 10-7 Ci/m3 ÷ 9700 Ci/gram = 2 x 10-11 grams/m3, or 0.00002 micrograms per cubic meter.

concentrations beyond the facility boundary are considerably lower than the MPC values given in the table.

A key unresolved issue in radiation standards at this writing is whether plutonium and perhaps certain other alpha emitters are more dangerous to health than was assumed in the derivation of the presently established MPCs for these isotopes. One element of the uncertainty has to do with

the "hot particle" question--essentially, whether the nonuniform irradiation of tissue that results from the short range of alpha particles is more effective in producing cancer than uniform deposition of the same amount of energy. [160] Another issue is whether the ICRP model of the way the lung clears itself of foreign particles, which was used to derive the present standards, is valid. [161] The few experiences of accidental exposure of humans to known doses of plutonium cannot yet resolve the question of insoluble plutonium's toxicity: in one case (Los Alamos, 1944/1945), only 3 people were exposed to the insoluble form; the other case (Rocky Flats, Colo., 1965) was too recent for most of the cancers that may eventually appear to have done so by 1976. [162] Although it seems likely as of late 1976 that the most pessimistic version of the hot-particle hypothesis will not turn out to be correct, informed opinion seems to be converging on the view that plutonium is 5 to 200 times more dangerous than the existing MPCs imply. [163] If this is the case, the difficulties of a nuclear power economy based on recycling plutonium and perhaps other alpha emitters will be significantly magnified.

It is important to emphasize that radiation standards and the corresponding MPCs are established with the goal of protecting *human* health, primarily against the delayed effects (cancer and genetic defects) expected to occur even at low doses and dose rates. Although radiation of course affects organisms other than human beings, no plant or other animal is known to be significantly more sensitive. Some reasons why this is so for cancer and genetic defects are clear enough. For radiationinduced cancer, with its typically long latency period, rather few nonhuman organisms survive the other rigors of existence long enough for an extra cancer risk caused by radiation to express itself. For genetic defects, as noted in the previous section, human ethics and medical technology see to it that many defects are preserved and propagated in the population; in nonhuman organisms, most mutations are removed by selection.

Finally, it may be observed that radioactive materials are often deemed dangerous (if the standards are any guide) in physical quantities far smaller than those characteristic of most other toxic compounds. The relatively good record of a small nuclear industry in containing these materials so far (see Chapter 8 for more discussion and some exceptions) must be tempered with recognition of the difficulty of maintaining the nearly flawless containment desired as the size of the nuclear enterprise grows.

THE ENVIRONMENT AND CANCER

While we spend our life asking questions about the nature of cancer and how to prevent it, society merrily produces oncogenic substances and permeates the environment with them. Society does not seem prepared to accept the sacrifices required for effective prevention of cancer.

-- Renato Dulbecco, *1975, on receipt of the Nobel Prize in medicine for his cancer research*.

Cancer is the disease that most strikes fear into the heart of the average American, and cancers now are responsible for almost one-fifth of all deaths in the United States (Figure 10-6). This is less than half the toll now taken by arterial diseases, but the long, slow death frequently associated with cancer and the seemingly random way it selects its victims gives cancer a special

horror. As biologist John Cairns, an expert on carcinogenesis, has said, "For some reason heart attacks and

[160]The hypothesis that nonuniform irradiation by insoluble particles of plutonium oxide in the lung can be much more effective at inducing cancer than uniform irradiation, and that the present standards (based on a uniform irradiation model) accordingly are several orders of magnitude too loose, was put forward by A. R. Tamplin and T. B. Cochran, *Radiation standards for hot particles*, and rebutted by W. J. Bair, et al., *A radiobiological assessment of the spacial distribution of radiation dose from inhaled plutonium*. See also the discussion of plutonium toxicity in Chapter 8.

[161]A critique of the ICRP model is J. W. Gofman, *The cancer hazard from inhaled plutonium*.

[162]J. Martin Brown, *Health, safety, and social issues of nuclear power*.

[163]K. Z. Morgan, *Suggested reduction*; Brown, *Health, safety and social issues*; J. T. Edsall, *Toxicity of plutonium and other actinides*; R. C. Thompson, *Transuranium element toxicity*.

strokes tend to be thought of as natural hazards of age, and either a normal end to a satisfactorily long life or, when they occur in middle-aged men, the wages of overeating and lack of exercise. In contrast, cancer is thought of as an unpredictable disease that strikes indiscriminately at rich and poor, fat and thin, old and middle-aged as if it usually owed nothing to external causes." [164]

It has, in fact, been almost exactly two centuries since external causes were first associated with cancer. In 1775 Sir Percival Pott published "Chirurgical observations relative to the cataract, the polypus of the nose, the cancer of the scrotum, the different kinds of ruptures, and the mortification of the toes and feet," in which he accurately noted that chimney sweeps were likely to contract cancer of the scrotum. It was a century later in 1875 that the next association was observed of an environmental factor with human cancer, when the induction of skin cancer was related to occupational exposure to coal tar (a substance chemically related to soot). [165] Many other examples of occupational carcinogenesis associated with such diverse substances as lubricating oils, dyestuffs, and radium paint were identified in the late nineteenth and early twentieth centuries. [166] And more recently cadmium, arsenic, asbestos, vinyl chloride, hair dyes, various pesticides, plutonium, and other materials to which those employed in certain industries are heavily exposed have been implicated (Box 10-5).

The degree of risk associated with occupational exposure to carcinogens can be quite spectacular. One-quarter of 366 males who worked in a coal tar dye plant in the United States between 1912 and 1962 contracted bladder cancer. [167] Considering how potent some chemical carcinogens appear to be, it is not surprising that the counties of the United States where the chemical industry is more highly concentrated show excessive rates of bladder, lung, liver, and certain other cancers among males. [168]

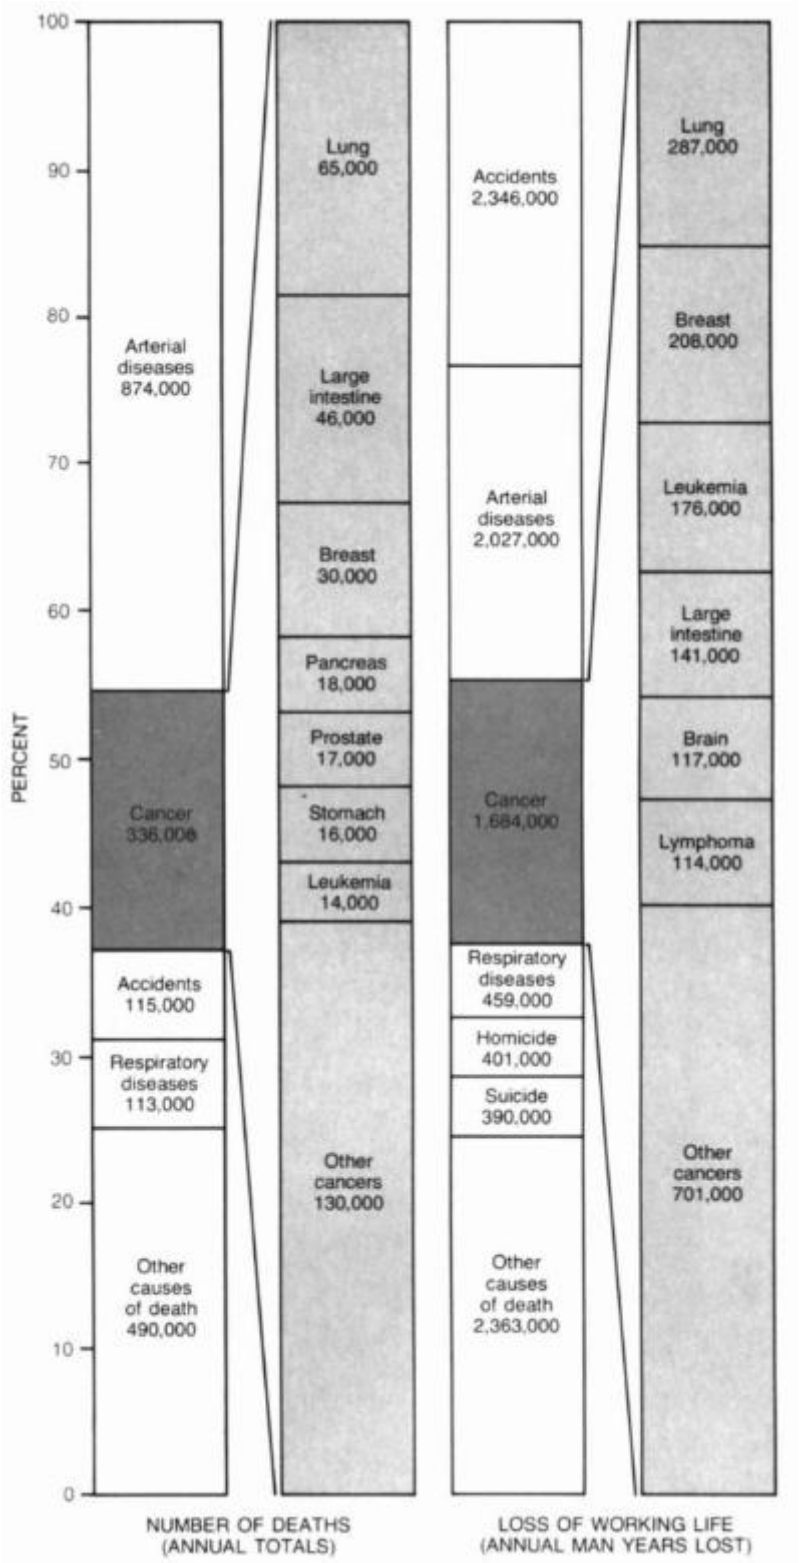

FIGURE 10-6 Deaths from cancer now make up almost a fifth of all deaths in the United States. Of the deaths attributed to cancer, more than 60 percent are caused by a few common forms of the disease. The remainder are distributed among more than 100 other cancers. The impact of each kind of cancer can also be judged from the shortening of life span it causes, measured here

in lost working years, with working life assumed to extend from age 20 to age 65. Among all causes of death, the principal effect of considering shortening of life span instead of simple mortality is to increase the importance of accidents; among cancers, it emphasizes the relatively high incidence of leukemia in young people. Lung cancer, however, is still predominant. (After J. Cairns, 1975.)

BOX 10-5 A Potpourri of Chemical Carcinogens

A number of chemical carcinogens have already been discussed in the sections on air pollution, pesticides, and so on. There are, however, numerous other chemical carcinogens and suspected chemical carcinogens that are not readily classified by structure, mode of contact, or pattern of utilization of the compound (see Figure 10-7). Some of the more important of these are discussed here.

Carcinogens in Tobacco Smoke

In the 1964 Report of the Advisory Committee to the Surgeon General of the U.S. Public Health Service, a long series of epidemiological studies were cited that clearly associated lung cancer with smoking. [a] Although a very few scientists still claim that there is no causation in the correlation (i.e., that some common factors make people both prone to smoking and prone to lung cancer, but that the first does not cause the second), most differences of opinion focus on the nature of the carcinogens in the smoke. The majority of scientists are sure they are chemical carcinogens (thousands of different chemicals are produced by incomplete burning of the tobacco). The particular culprits might be polycyclic hydrocarbons (organic compounds having several fused rings--see Figure 10-7). Cigarette smoke condensate and various chemical fractions of it are quite mutagenic [b] and cause malignant transformation in tissue culture. [c] One researcher has argued, however, that the carcinogenicity of tobacco smoke is due to radioactive polonium, which collects on tobacco leaves. [d]

Asbestos

A rare form of cancer, mesothelioma, developing in the "skin" membranes lining chest and abdominal cavities, is strongly correlated with exposure to asbestos. [e] This substance is also implicated in cancer of the larynx, lung, and gastrointestinal tract. [f] About one-half of asbestos workers die of cancer, and the risks extend to the workers' wives and families, who are exposed to asbestos dust and fibers on workclothes. Furthermore, there is evidence from studies of

asbestos workers that smoking and asbestos exposure act synergistically in producing cancer; that is, the risk of cancer to those exposed to both asbestos and smoking is very much greater than the sum of the risks of those exposed to one or the other. [g]

The general public is exposed to asbestos fibers in the air from brake drums, insulation, and the like, and in food and water from diverse sources. One of the most publicized pollution cases of the 1970s involved the contamination of Lake Superior with asbestos or asbestos-like fibers from taconite tailings being dumped in the lake by the Reserve Mining Company. [h]

Arsenic

Long known to be poisonous, arsenic has now been shown to be almost certainly involved in producing both respiratory and skin cancers in human beings. Male smelter workers show a strong correlation between degree of exposure to arsenic and incidence of respiratory cancers, although sulphur dioxide cannot be eliminated as a possible cause. [i]

In a local area of the southwest coast of Taiwan, water from artesian wells contains a high concentration of arsenic. Again, "the prevalence rate for skin cancer showed an ascending gradient according to the arsenic content of the well water, that is, the higher the arsenic content, the more patients with skin cancer." [j]

Nitrosamines

Nitrites are widely distributed in the environment and are commonly used in curing meat and fish. Nitrates are also common in soils and plants, as are microorganisms capable of reducing nitrates to nitrites. Secondary amines [k] may be present in a variety of foods, including cereals, mushrooms, various vegetables and fruits, fish, cheese, tea, wine, and beer. They are also found in some drugs. These amines have been shown to react with nitrite to form nitrosamines, some of which are potent carcinogens. Human beings may take in nitrosamines directly from the environment, or they may be synthesized from

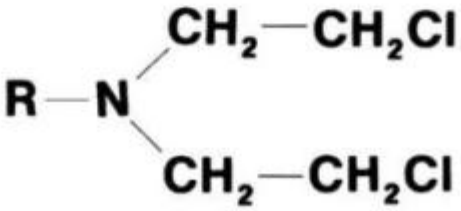
nitrite and secondary amines in the digestive tract. The degree of risk from nitrosamines is not certain at the moment, but a program at least to reduce the levels of their precursors in the diet would seem prudent. [l] Individuals can do this, for instance, by restricting their intake of cured meats, which contain large amounts of nitrates. Taking Vitamin C along with foods high in nitrites may help; there is some evidence that Vitamin C can block the synthesis of nitrosamines in the digestive tract. [m]

Hormones in Animal Products and Other Food Additives



Something on the order of 2500 different substances are being purposely added to the U.S. food supply. Most are added directly, but some are added indirectly by injection or implantation, or in animal feed. These substances include hormones and antibiotics which are used to promote growth and health in animals, and flavorings, colorings, preservatives, emulsifiers, stabilizers, and so on, added to processed foods. [n] Several of these substances have been implicated as carcinogens. For instance, diethylstilbestrol (DES), formerly fed to up to three-quarters of the cattle slaughtered in the United States, was connected with a rare kind of vaginal cancer

affecting the *daughters* of women treated with DES to prevent threatened miscarriage. DES had also been shown to cause tumors in mice as early as 1964. These discoveries led to a regulatory mess that Nicholas Wade of Science magazine described in 1972 as follows: "The history of the attempt to control DES is a record that includes negligence, deception, and suppression by the USDA (U.S. Department of Agriculture) and prevarication by the FDA (Food and Drug Administration)." [o] The FDA did eventually ban DES, but the ban was reversed by the U.S. Court of Appeals in January 1974. Subsequently, the FDA revoked approved methods of identifying DES in meat, effectively banning it again. [p] The issue of the safety of estrogenic

hormones as feed additives and implanted pellets is extremely complex, especially since similar hormones are present in human beings. The entire issue remains unresolved. [q]

Controversy has also marked the banning of other carcinogenic food additives, from cyclamates to red dye no. 2. [r] Much of the debate has centered on the Delaney clause. The clause, part of the U.S. Food, Drug, and Cosmetic Act of 1958, was named after its sponsor, Congressman James J. Delaney of New York. It states "no (food) additive shall be deemed to be safe if it is found to induce cancer when ingested by man or (Continued)

BOX 10-5 (Continued) animal or if it is found, after tests which are appropriate for the evaluation of the safety of food additives, to induce cancer in man or animal." The food industry, with an enormous financial stake in many additives, and some scientists have argued that the Delaney clause is "unscientific" -- largely because it leads to the banning of substances that have been shown to cause cancer after experiments in which animals were exposed to extremely high doses. The basis of this criticism is the hypothesis that there is a threshold dose below which the chemical will be noncarcinogenic. This hypothesis is rejected by most experts in the field, who support the Delaney clause as a necessary conservative bulwark against cancer caused by food additives. [s] Another common claim is that virtually anything in high enough doses will cause cancer -- a claim that is simply false.

We conclude this sampling of the problems of chemical induction of cancers with the observation that they are not caused only by chemicals that human beings manufacture or deliberately expose themselves to. The high incidence of liver cancer in Africa and certain other tropical areas is associated with a product produced by the fungus *Aspergillus flavus*. The substance, *aflatoxin*, is an extremely potent carcinogen. The fungus grows on grain and root crops stored in humid conditions. The carcinogenic properties of aflatoxin were first suspected when a large number of turkeys died in Great Britain after being fed peanuts contaminated with *Aspergillus flavus*. [t]

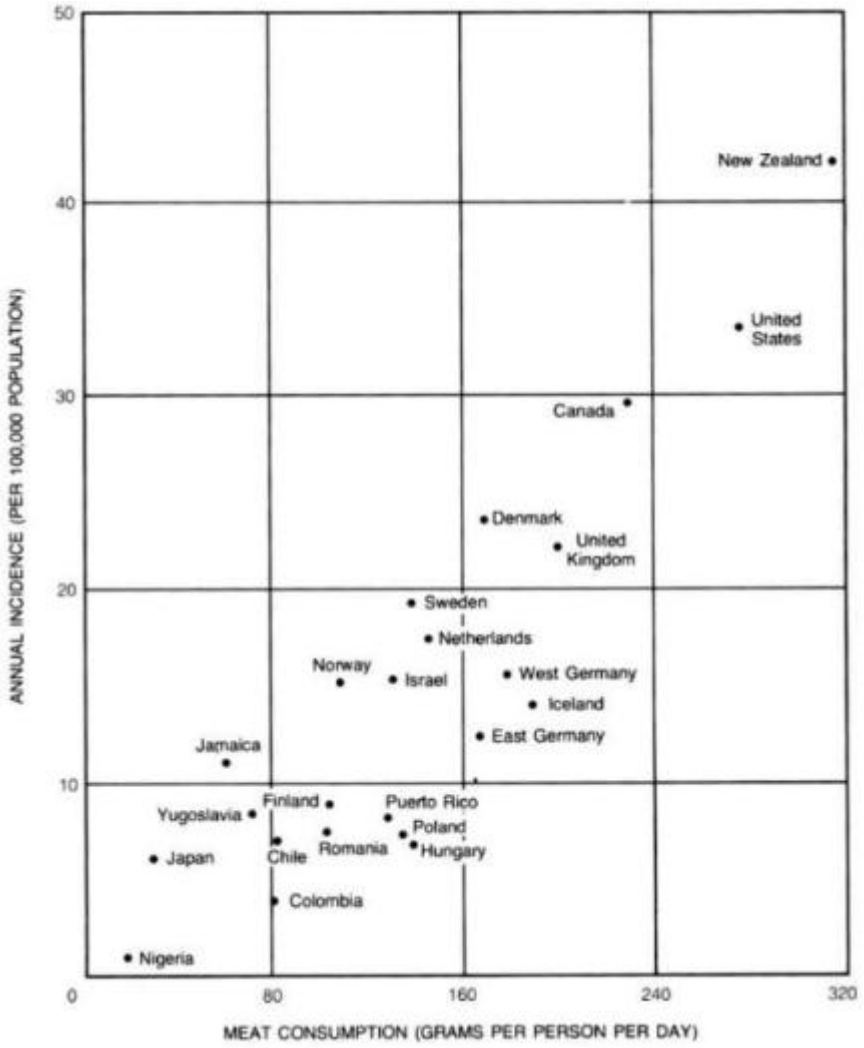

FIGURE 10-8 Geography of a cancer suggests a probable cause of the disease. The incidence of cancer of the large intestine among women in twenty-three countries is closely related to per-capita meat consumption in those countries. The data are adjusted to eliminate differences in age composition of the populations. An alternative explanation attributes cancer of the large intestine to a low consumption of cereals. The two hypotheses are hard to distinguish because high meat consumption and low cereal consumption tend to go together. (After J. Cairns, 1975.)

[t]Harris, *Cancer and the environment*, p. 60; Denis P. Burkitt, *Cancer and environment*.

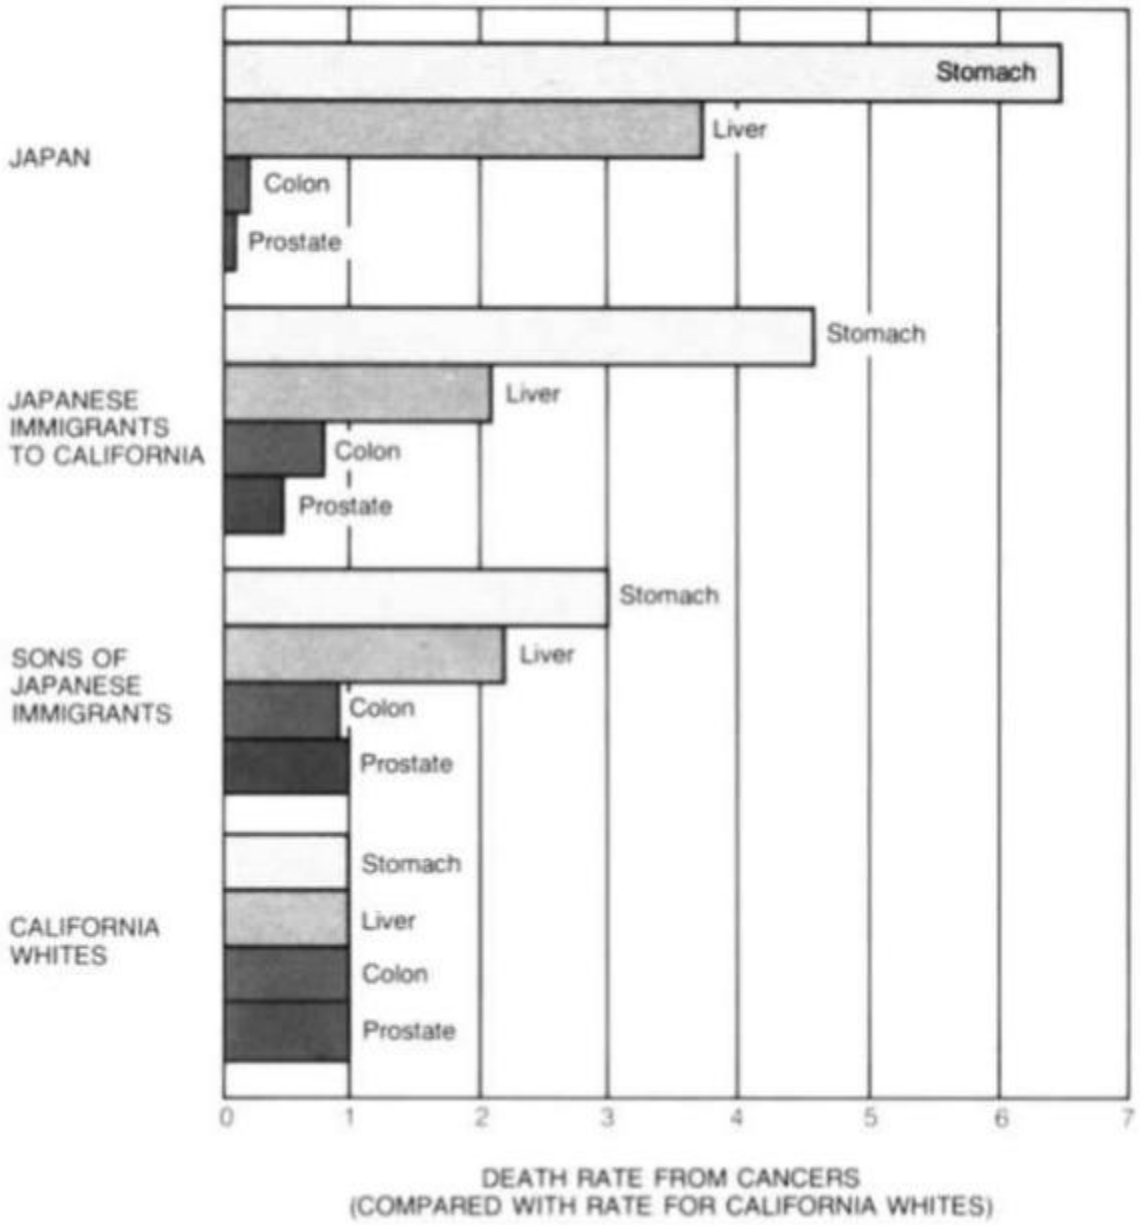

FIGURE 10-9 Change in the incidence of various cancers with migration from Japan to the United States provides evidence that the cancers are caused by components of the environment that differ in the two countries. The incidence of each kind of cancer is expressed as the ratio of the death rate in the population being compared to that in a hypothetical population of California whites with the same age distribution; the death rates for whites are thus defined as 1. The death rates among immigrants and their children tend consistently toward California norms, but the change requires more than a generation, suggesting that causative agents are factors influenced by culture rather than hazards to which all are exposed equally. (After J. Cairns, 1975.)

It was the uneven geographic distribution of many cancers that provided a major clue to their environmental origin. For example, Kangri cancer occurs in the abdominal wall of the Kangris of Tibet; the Kangris carry pots of heated charcoal under their clothes for warmth. Stomach cancer is much more common in Japan than in most other nations, and the incidence is high also in

Iceland and Finland. The reasons for these foci are still obscure. Burkett's lymphoma is found commonly only in warm, moist areas, especially Africa and New Guinea, and seems to be associated with chronic malaria. Skin cancers are caused by ultraviolet radiation and are more common in sunny climes. Cancer of the bowel is the second most common cancer in most of Europe, North America, and New Zealand, but is rare in LDCS. It is thought that it is related to eating a great deal of animal fat, or possibly to low consumption of cereals (Figure 10-8). The list of geographic correlations is a long one, which we have only sampled. [169]

Further evidence of the environmental origins of various cancers is found in data on migrants. For example, when Japanese move to the United States, the high level of stomach cancer among them tends to disappear, and the frequency of other cancers tends to converge with that of white Americans (Figure 10-9). The patterns can be explained by gradual changes in such cultural factors as diet.

Despite the early and extensive association of cancers with exposure of workers to various chemicals and to radiation, and despite the extensive geographic correlations, only recently has the environmental induction of nearly all cancers been widely recognized. It is now generally accepted that *at least three-quarters of human cancers are "environmental" in origin* (that is, not caused

[169]For further examples, see R. J. C. Harris, *Cancer and the environment*; and D. P. Burkitt, *Cancer and environment*.

by viruses, spontaneous breakdown of immune mechanisms, and the like). [170]

The exact mechanism of carcinogenesis remains a mystery, though much recent evidence supports the old theory that mutation within a body cell may be the key initiating event in most environmental carcinogenesis. [171] This evidence shows that carcinogens function by mutating the genetic apparatus (DNA) of a cell, altering its hereditary properties in ways that lead to its uncontrolled proliferation. Almost all chemical carcinogens appear to interact directly with the base pairs of DNA molecules or to be metabolized by the body to active forms that interact with the DNA. [172] There are different types of these mutagenic active forms that can produce frameshift mutations or base-pair substitutions, which alter the genetic message coded into the base sequence of the molecules. [173]

The picture of carcinogenicity that is gradually emerging is one in which somatic mutations (those occurring in body cells other than those that produce sperm or eggs) lead to the production of new lines of genetically identical cells (clones) that are "fitter" than other lines. That is, the new clones are able to outreproduce other clones and, freed of the normal constraints on cell reproduction, invade other adjacent tissues. [174] The lethality of cancers is, however, strongly associated with the ability of cancerous clones not only to invade neighboring tissues, but also to colonize distant tissues -that is, to *metastasize*. Therefore, whatever genetic changes occur in the cell must also produce the ability of cells swept into blood or lymphatic circulation to found cell colonies in alien tissues where cell-cell interactions are unlike those of the tissue where the

cancer clone got its start. There does not seem to be any universal metastatic ability (cancers normally colonize rather specific tissues). For instance, lung cancers tend to move to adrenal glands and brain, prostate cancers to the bones, and brain cancers normally are not metastatic. [175]

One theory of carcinogenesis holds that each cell is prevented from becoming cancerous by a series of genes. What is required for a cancer to start up, according to this model, is a series of mutational steps. First a normal cell must be subject to a mutational event that alters one of the restraining genes but that does not so damage the cell that it cannot reproduce. This cell carrying the somatic mutation then gives rise by cell division to a clone of mutant cells, each lacking one restraining gene. In turn, a viable mutation in the new line may lead to a clone lacking two of the restraints. Repeats of this process eventually lead to a precancerous state (perhaps a benign growth) and then a full-blown malignancy. This hypothetical process is diagramed in Figure 10-10.

Models of carcinogenesis, in which a sequence of subcellular events culminates in cancer, have great appeal because they lead to an explanation of two of the most important features of cancers. One is the common pattern of increased incidence with age (there are a few exceptions to this) and the other the long latent period (often 20 years or more) that seems frequently to occur between first exposure to carcinogens and the clinical appearance of the disease. A striking example is cancer of the penis, a rare cancer found only in elderly men. It can be prevented by circumcision in the first few days of life, but may occur if circumcision is delayed for only a few years. [176] The carcinogenic process in this case must be initiated early in life -- perhaps some substance that accumulates under the foreskins of babies is capable of causing an "initiating" mutation that alters a key restraining gene or otherwise makes the tissue susceptible to a later "precipitating" step or steps, which produce the actual cancer. [177]

Whatever the actual mechanism of carcinogenesis, it is clear that one must not search for the cause of a particular cancer only in the immediate past environment of its

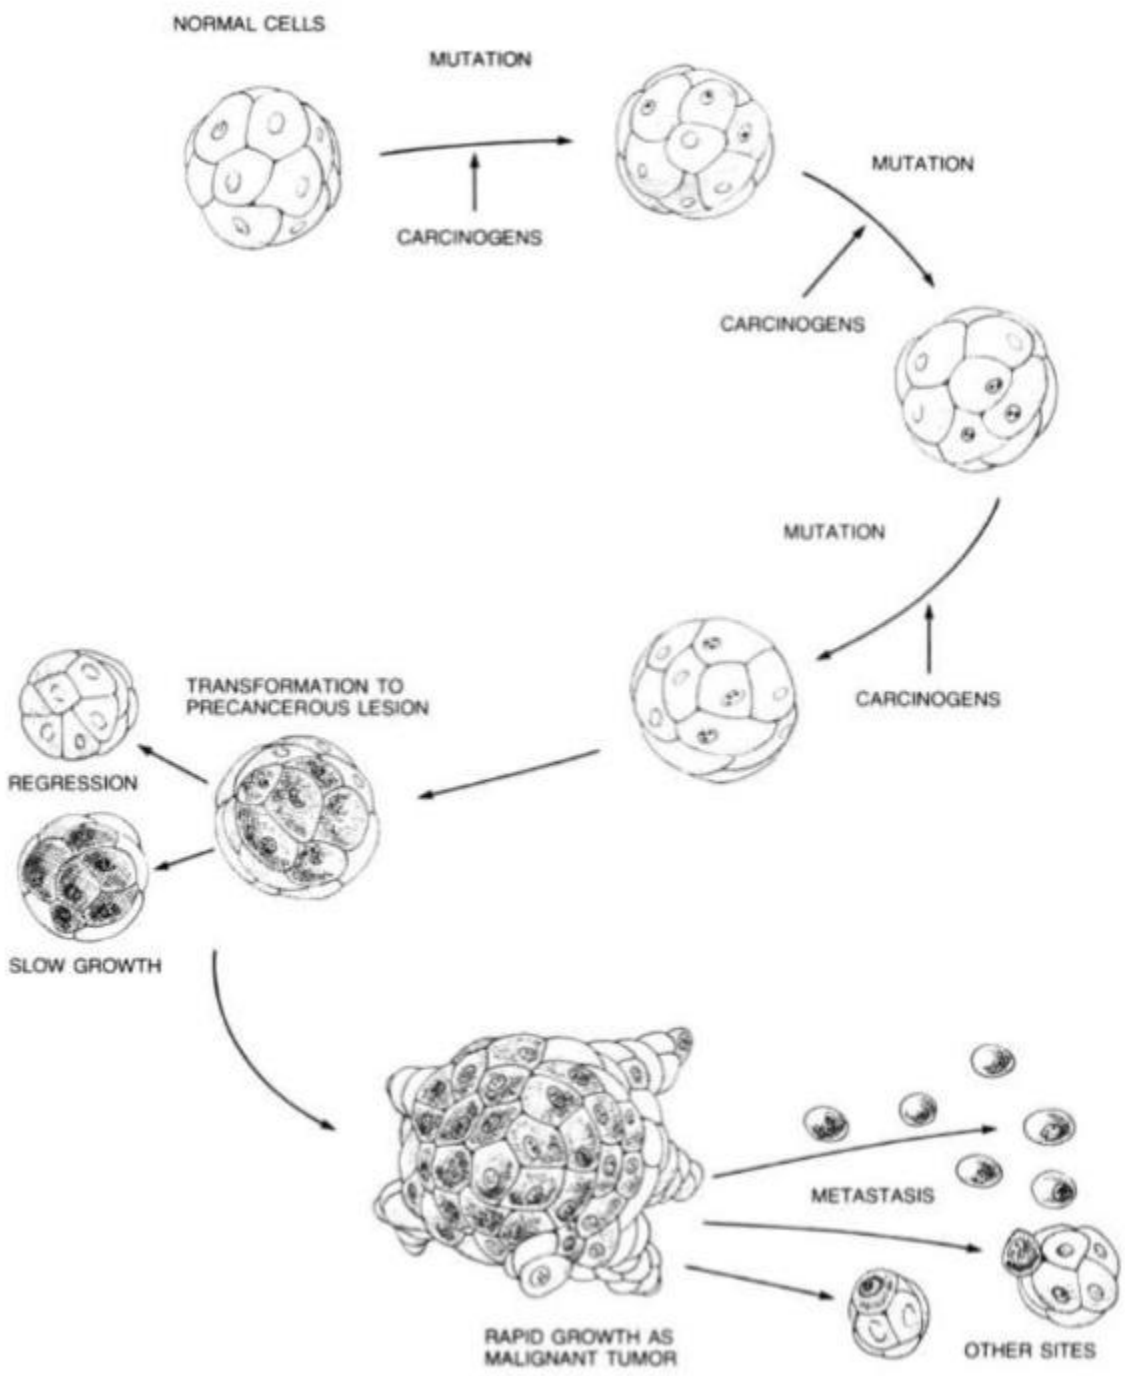

FIGURE 10-10 One theory of carcinogenesis states that cells are restrained from becoming cancerous by several independent genes and that tumors develop only when mutations accumulate in all those genes within a single line of cells. The mutations (black dots within cell nuclei) are seldom spontaneous but are apparently caused by carcinogenic factors in the environment. Once a precancerous lesion has formed, it must in many cases regress or grow very slowly; only a few lesions progress to an invasive, metastasizing tumor. (After J. Cairns, 1975.)

victims. For example, in several nations the occurrence of lung cancer is correlated not with present smoking habits but with cigarette consumption 20 years ago. [178] Equally, if a new carcinogen is introduced into the environment today, it may be two or three decades before the cancers it causes begin to show up in the mortality tables.

The problem of the latent period thus greatly enhances the difficulty of evaluating the carcinogenic hazards of various environmental factors. In retrospective studies it is often difficult to determine exposure levels in the distant past. In prospective studies it may be necessary to wait 30 or more years for definitive results. For these reasons scientists have tended to move toward studies of carcinogenesis in nonhuman organisms, where short life histories greatly reduce the problem of the latent period, and careful experimental exposures to suspected carcinogens are possible.

Almost all tests of carcinogenicity are done in rats and mice, although some suspected carcinogens have been tested in studies with dogs (notably beagles, in the case of plutonium). When tumors are induced in the experimental animals, it is clear only that the test substance can produce cancer in the experimental system. The question of carcinogenicity in human beings remains open. In general, if a substance is carcinogenic in one mammal, it will be in another, although exceptions are known. For example, 2-napthylamine is a potent inducer of bladder cancer in dogs, monkeys, and people, but not in mice, rats, guinea pigs, or rabbits. [179]

A further complication of animal tests is the need to use very high doses of the substance being screened -- the usual recommendation being that the maximally tolerated dose (MTD) be administered. (The MTD is that dose producing neither weight loss nor increased noncancer mortality.) The use of the MTD is necessary because of the small numbers of animals used in tests (often around 50). For example, if a carcinogen produced one cancer in each 100 human beings exposed (more than 2 million cancers if the entire U.S. population were exposed), the chances of detecting carcinogenicity in an experimental group of 50 mice with the same equivalent dose and susceptibility are essentially zero. Indeed, some 8000 mice would have to be treated (with 8000 controls) to produce a reasonably certain demonstration [180] that the material could induce cancer if there were the usual number of tumors in the controls. (The numbers given are based on a 10 percent incidence of tumors in the controls, which is common.)

When animal tests do reveal a substance to be carcinogenic, attempts to halt its use or restrict exposures are often protested on the grounds that mouse cancers are not human cancers and that the doses used in the experiments were unreasonably large ("a 165-pound man would have to eat 45,000 pounds of bacon a day every day for 600 days to get the same effect"). [181] But there is no way to demonstrate that an animal carcinogen will not produce human cancers at some dose level or in some human groups or in combination with some other substance. The high experimental doses, of course, are required to permit detection of carcinogenesis in small test groups of animals. Furthermore, it is just as likely that people would be even more susceptible to the carcinogen than the test animals as that they would be less so. For these and related reasons it is impossible to determine a safe dose of a known carcinogen -- which is the *raison d'être* of the 1958 Delaney Amendment, which establishes a "zero tolerance" for food additives that produce cancers in any test animals (Box 10-5).

The properties of carcinogenic materials (structure of chemical compounds, type of ionizing radiation emitted) are obviously related to their ability to intervene in cellular machinery. As noted in the discussion of radiation, it is already possible to make a reasonable prediction about the dangers of a radiation source on the basis of the kind and energy of the emission (alpha, beta, gamma, neutron, and so on) and where inside or outside the body the emission takes place. Similarly, members of certain groups of chemical compounds such as polycyclic hydrocarbons (organic compounds with a multiple ring structure -- benzpyrene, benzanthracene, and the like) are always suspect because of the kinds of reactions to which

---

[178] Ibid.

[179] Epstein, *Environmental determinants*, p. 2427. Material in the following paragraph is also derived largely from this source.

[180] Probability would be less than 0.05 that the observed difference between treated and control mice was due to chance alone.

[181] Dr. William Sherman of the National Livestock and Meat Board, commenting on tests on rats of the carcinogenicity of nitrates--compounds used in curing bacon (*Palo Alto Times*, February 13, 1976).

their structure makes them prone. The identification of chemical carcinogens is complicated, however, by accumulating evidence that noncarcinogenic environmental pollutants are often transformed into carcinogens by the machinery of the body and that it is these end products that share the key chemical properties. [182] This is not surprising, considering the phenomenon of activation of chemical mutagens discussed previously and the apparent relationship between mutagenesis and carcinogenesis. This activation phenomenon may be one of the reasons for those differences in susceptibility to the same compound among different species. In the tissues of a fruit fly a given compound may be broken down into harmless metabolites; in the tissues of a human being they may be converted into a potent cancer-inducing agent.

One of the most hopeful signs in the battle against chemical carcinogens has been the recent development of the Ames test. Biochemist Bruce Ames of the University of California at Berkeley and his colleagues have invented a system that employs a set of strains of the bacterium *Salmonella typhimurium* to test a chemical for mutagenicity. The strains are especially sensitive to mutagens for several reasons. One is that a repair system (present in all normal living things) that monitors DNA and corrects most but not all of the damage has been eliminated in the test bacteria. [183] The mutant strains cannot grow normally because they are unable to synthesize the amino acid histidine. When the billion or more bacteria in a test plate are exposed to a mutagen, however, there is a good chance that the defective DNA code sequence of at least one bacterium will be changed back into a sequence that properly codes for the manufacture of histidine. Such a "reverted" mutant bacterium will then be the founder of a normally growing colony on the plate. The level of activity of a given mutagen will be related to the number of reverted colonies per test plate. The test combines on a single Petri plate these bacteria and a rat (or human autopsy) liver homogenate, which provides the mammalian metabolism that converts procarcinogens to their active mutagenic forms.

The success of the Ames test has itself added to the evidence that cancers are initiated by somatic mutations. In initial studies, eighteen known polycyclic chemical carcinogens were shown by Ames and his colleagues [184] to be potent mutagens after they were "activated" (converted to mutagenic form) by liver enzymes from rats and human beings. Subsequent studies proved 157 (90 percent) of 175 known carcinogens mutagenic, while of 108 "noncarcinogens" only 14 gave positive test results, and many of these may be due to the statistical limitations of animal cancer tests for showing noncarcinogenicity. Japan for eight years permitted use of furylfuramide as a food additive after it had been "cleared" of carcinogenicity in two sets of animal experiments. After it was later shown to be mutagenic in bacteria it was reevaluated and found to be a carcinogen in another animal test. [185]

The great advantages of the Ames test as a tool for detecting environmental carcinogens are its sensitivity and speed and the low cost of screening a compound. A standard test by the National Cancer Institute (NCI) using mice or rats costs roughly $100,000 and takes three years. [186] A test with the Ames screen costs roughly $200 and takes three days! [187]

That the enormously expensive War on Cancer has been a catastrophic failure has been widely recognized. Most of the statistical progress in cancer survival rates apparently has not come from that war but from reduced death rates on operating tables attributable to improved surgical techniques and use of antibiotics to stem postsurgical infections. [188]

Two factors have been responsible for the failure. First, eager politicians have poured vast amounts of money into seeking a "cure," on the unlikely assumption that cancer was a single disease amenable to treatment with a single miracle drug. This trend was opposed by

knowledgeable molecular biologists who understood that information about the basic mechanisms of cancer was inadequate to justify such an effort. Among biologists, the "war" was often compared to trying to send men to the moon before the discovery of Newton's laws of motion.

The second factor was a lack of recognition that cancers are largely environmentally caused, with a resultant distortion of research priorities toward cure rather than prevention -- and toward "high-powered" science. The scientists most involved in the "war" were largely recruited from the ranks of surgeons, biochemists, radiologists, and virologists -- mostly people with little interest in studying the release of carcinogens into the environment or the possible nutritive factors involved in the induction of cancers. This has led, for example, to a continued expenditure of more than $50 million annually into the unsuccessful and unpromising search for human cancer viruses, compared to only $3 million spent on nutritional investigation. As the distinguished science reporter Daniel Greenberg, put it, "A partial explanation is that nutrition is a low prestige field, and easily evokes the image of high school cafeteria dieticians, whereas virology wins Nobel prizes." [189]

Cancer researcher Dr. Philippe Shubik recently summed up the situation in a statement to the National Cancer Advisory Board: "It is a universal opinion that cancer can be attributed to environmental factors in the main. . . . Cancer is largely a preventable disease." [190] Whether his words will be heeded remains an open question. In the mid-1970s it appeared likely that billions of dollars will be spent during the rest of this century, attempting to cure people whose sickness could have been prevented.

NOISE POLLUTION

Noise pollution as a widespread phenomenon is as old as the industrial age. The problem recently has been thrown into sharp focus by the discovery that some teenagers were suffering permanent hearing loss following long exposures to amplified rock music, and by public concern

TABLE 10-17
Noise Levels (in decibels)

Food blender	80
Niagara Falls at base	90
Heavy automobile traffic, or jet aircraft passing overhead	100
Jet aircraft taking off, or machine gun at close range	120

about the effects of sonic booms caused by supersonic transports (SST). But noise pollution is much more pervasive than these extreme examples indicate. Studies of nonindustrialized peoples

in Africa and India have indicated that progressive loss of hearing with age, which is universal in industrial societies, is not a natural part of aging but a consequence of the noisy modern environment. [191]

Noise is usually measured in decibels (abbreviated *db*). A tenfold increase in the strength of a sound adds 10 units on the decibel scale; a 100-fold increase adds 20. Silence, defined somewhat arbitrarily as the average human threshold of hearing, is represented as zero decibels. The formal definition of the decibel scale is

$$\text{decibels} = 10 \log_{10} \left(\frac{\text{measured intensity}}{\text{average human hearing threshold intensity}} \right)$$

. Table 10-17 gives the decibel values of some representative sounds. Actually, the human ear responds differently to different sound frequencies; high-frequency sounds are perceived as louder than low-frequency sounds of the same actual intensity. Accordingly, many investigations of noise pollution employ a weighted scale that accounts for the sensitivity of the human ear. It is called the "A-weighted scale of sound levels," and its units are abbreviated "db(A)."

Even a brief exposure to intense noise can cause temporary loss of hearing acuity. Permanent loss of hearing follows chronic exposure to high noise levels. Noise levels as low as 50 to 55 decibels may delay or

[189]Stalemate, p. 25.
[190]Quoted by Lewin, *Bacteria to be used*.
[191]ReVelle and ReVelle, *Sourcebook*,. p. 162.

interfere with sleep and result in a feeling of fatigue on awakening. Recently there has been growing evidence that noise in the 90-decibel range may cause irreversible changes in the autonomic nervous system. Noise may be a factor in many stress-related diseases, such as peptic ulcer and hypertension, although present evidence is only circumstantial. [192] Not surprisingly, noise can also cause stress and other physiological disturbances in animals other than people, including reproductive problems and altered predator-prey relations. [193]

Noise pollution is clearly a growing threat to health and happiness. Even if the biosphere is not subjected to the booms of large-scale commercial use of the SST, the need for noise abatement will continue to be serious. Unless action is taken against the proliferation of motorcycles, "tote-goats," power lawnmowers, motorboats, noisy appliances, and the like, they will make aural tranquility, even in the wilderness, a thing of the past. Possibly, however, this problem will prove to be more readily solvable with technology, imagination, and determination than most pollution problems.

THE WORK ENVIRONMENT

Serious as the general environmental levels of chemical pollutants, radiation, and noise may be, exposure to such insults in the work environment is usually much more intense. This is cause for great concern for a number of reasons. The first, of course, is concern for the lives of the individuals exposed to the hazard, even when those exposed are a tiny fraction of the population (as, for example, in the case of the uranium miners discussed in Chapter 8). Second, very large numbers of people are occupationally assaulted by high concentrations of some dangerous substances (e.g., asbestos, vinyl chloride, benzpyrene). Third, the effects of occupational exposure extend beyond the working population. Asbestos fibers on workmen's clothes threaten their families and friends; mutated genes in workers exposed to radiological or chemical mutagens are spread into the population outside of the workplace. And fourth, inadequate standards for the confinement of dangerous substances in the workplace make them a focus for contamination of adjacent areas or for accidental contact with nonworkers. A woman living downwind from a plant using vinyl chloride died of *hemangiosarcoma*, [194] a rare cancer associated with this chemical. [195] A child who dipped one finger into an open can of TEPP (tetraethylpyrophosphate, an extremely toxic pesticide--see Appendix 3) later sucked the finger and died. [196]

Every year some 100,000 to 0200,000 new synthetic chemicals are made available to industry and about 500 go into commercial use. [197] But to date, the hazards associated with only about 500 chemicals altogether have been evaluated and some sorts of exposure standards established. Society in essence is playing Russian roulette with the untested chemicals now in use and the largely untested annual flood of new ones.

The problems of protecting workers and the general public are exemplified by the vinyl chloride (VC) story. VC, a chlorinated hydrocarbon, is not a rare chemical found only in a few laboratories or one to which only a few workers are exposed. VC itself is used as an aerosol propellant for solvents. More importantly, it is a key component of the pervasive plastic polyvinyl chloride (PVC), from which the VC frequently escapes. PVC is found almost everywhere -- in records, boots, furniture, wrapping paper, electrical insulation, pipes, and films. It is estimated to contribute $12 billion to the U.S. gross national product annually. Worldwide, plants producing VC and PVC employ an estimated 70,000 workers, and millions work in plants where VC and PVC are used. Perhaps one-third of humanity is daily exposed to PVC in one form or another. [198]

The economic stakes involved with VC are clearly enormous. It is therefore not surprising that the giant chemical corporations involved in production of 12 million tons of it per year [199] were slow to accept the evidence that it was carcinogenic. In the face of building

evidence that the compound could have serious health effects, they pressed to retain old standards that allowed workers to be exposed to VC at concentrations of 1500 milligrams per cubic meter (mg/m^3) of air. In April 1974 the Occupational Safety and Health Administration (OSHA), in response to the deaths of four workers from hemangiosarcoma, issued a temporary emergency standard of 150 mg/m^3. In October of the same year, a permanent standard of 3 mg/m^3 (1 ppm of vinyl chloride gas) was established. The final standard was established only after legal appeals by the industry had been struck down in court. [200] Industry argued, among other things, that they could not refine their measuring techniques sufficiently to meet the new standards. This statement was patently false. Indeed, "In many cases the same corporations who testified that the technology is not available were the same corporations which have contracted with the Department of Defense to develop these monitoring devices." Source: Margareta Winell, An international comparison of hygienic standards for chemicals in the work environment.

The problems of protecting people from chemical, radiological, and physical [202] insult in the workplace are very complex. Society, for example, has clearly decided that conditions within the workplace 10 to 100 times worse than those encountered outside of it are tolerable -- as differing standards set by the Environmental Protection Agency (EPA) and OSHA show. For example, it is permissible for a worker in the United States to be exposed for eight hours daily to 13 mg/m^3 of sulfur dioxide, whereas EPA limits for the general public are exceeded if the concentration goes above 1.3 mg/m^3 for three hours once a year. [203] Even accepting this assumption, it remains extremely difficult to assess the actual hazards associated with exposure to the level allowed.

Although nations that establish standards for exposure presumably all have the same goal, those standards vary a great deal from country to country (Table 10-18). For example, standards tend to be much more rigorous in the

[202] See, for example, I. Ostrand et al., *Heat stress in occupational work*.

[203] B. Commoner, *Workplace burden*.

Soviet Union than in the United States, especially for substances like chlorinated hydrocarbons, which affect the central nervous system, and alkylating agents such as ethylene imine, which generally are mutagenic. [204] In a less developed country like India, concentrations of many substances above the OSHA limits are regularly encountered. [205] In the latter case, deleterious effects may be exacerbated by the general poor health and nutrition of the workers.

An especially vexing problem is that of carcinogenesis in the workplace, which may even differentially affect workers in different parts of the same industrial plant. [206] A major difficulty with cancer prevention is, of course, the latent period -- the time between first exposure to an occupational carcinogen and the first clinical evidence of cancer. This period is usually 20 to 35

years, although it may be as short as 10 years or as long as 50 or more. [207] Until satisfactory screening procedures are developed (and the Ames test should be a big help here) and are coupled with rigorous controls, workers will continue to play the role of guinea pigs.

It is very important that unions become even more deeply involved in these problems -- especially in seeing that more research on health hazards is done, coordinated internationally, and carried out by agencies other than corporations, which may have a vested interest in the results. They can also work to see that physicians are better informed on the hazards peculiar to various work environments and also, through political action, see to it that standards are set conservatively and are enforced rigorously.

If the unions do not get the job done, it won't be done, because the initiative clearly will not come from government or industry. Charles Levinson, secretary general of the International Federation of Chemical and General Workers Union, the union that led the worldwide fight to improve VC standards, put it very well:

> The battles to control already known hazards, such as asbestos, vinyl chloride and arsenic have yet to be won by the workers. The latency period for effective legislation to control industrial cancers appears to be longer than the latency period of the disease. The key to the problem is not in the scientific lag, but rather the economic and political lag. The familiar slogan "Safety Pays" is really a cruel joke. Safety does not pay, it costs. It costs corporations money to be safe; it takes money to finance studies on occupation diseases; it costs in down-time when a noxious or lethal substance floods the workplace; it costs in efficiency when workers have to wear respirators at their jobs. These costs do not add a penny to the balance sheets. The profit-motivated allocation of resources within a company does not often permit a high priority for industrial safety. [208]

GEOLOGICAL HAZARDS

Geological hazards, such as landslides -- or even earthquakes -- are sometimes caused by human activities. These include changing the contours of land for housing or industrial construction or building large dams to meet the needs of growing populations for additional supplies of fresh water.

When Lake Mead was filled (1939) following the completion of Hoover Dam, thousands of seismic events -- the largest of which was an earthquake with a magnitude of 5 on the Richter scale -- were recorded in that previously inactive area. Large dams in other usually inactive regions of the world have caused numerous earthquakes with magnitudes greater than 6, large enough to do substantial damage to urban areas. An earthquake that registered 6.4 on the Richter scale was triggered by the filling of the Kogna Dam in India in 1967, causing 200 deaths. [209] Some geologists suspect that the lowering of water tables, now a worldwide occurrence, could have similar effects.

In 1967 the consequences of four years of pumping fluid chemical wastes into an underground reservoir near Denver became clear. A series of earthquakes occurred, the three largest of which had magnitudes of about 5; slight damage was reported in Denver. The amount of

[209]G. J. F. MacDonald, *The modification of the planet Earth by man*.

energy released in the series of earthquakes was slightly greater than that released by a 1-kiloton atomic bomb, more energy than was expended in pumping the fluid into the reservoir. The remaining energy had been stored in the Earth's crust by geologic processes, and its release was triggered by the injection of fluid into the underground reservoir. [210]

In 1963, the bottom of the Baldwin Hills reservoir in the Los Angeles area ruptured, causing water to burst through the dam, flooding suburbs below. Fortunately, there was enough warning that the inhabitants could be evacuated in time. The cause of the reservoir failure was eventually traced to the fact that it had been situated over ancient faults, which evidently were reactivated by fluid injection in nearby oil fields for oil recovery and waste disposal. [211]

Underground nuclear explosions also have the potential for releasing such stored energy. Although the widely discussed Amchitka test in 1971 did not induce a major quake, that in no way guarantees that future tests will not serve as triggers to set off earthquakes that may be far more serious than any yet caused by human intervention in the dynamics of the Earth's crust. On the other hand, knowledge gained from underground injections and explosions may permit use of them to relieve stresses that, if allowed to accumulate, could lead to major earthquakes.

Another human-induced geological hazard is ground subsidence. The problem here is the destruction of homes and other structures when the surface sinks due to the removal of water, oil, or large quantities of ore from beneath. [211a]

In addition to humanity's capability of triggering geological misfortunes, poor planning, partly abetted by rapid population growth, increases the impact of natural geological phenomena. Thus homes and apartment buildings have been built on potentially unstable landfill in the earthquake-prone San Francisco Bay area, schools and homes sit virtually astride the infamous San Andreas fault in the same vicinity, and residences cover steep hills subject to downhill creep and mudslides in the wet season. An equally absurd situation is heavy settlement in floodplains. (How, then, can the inevitable flood be called a natural disaster?) This problem has often been compounded by clear-cut logging of associated watersheds, which destroys the ability of the land to retain water and thus intensifies flooding (see also Chapter 6).

THE HUMAN ENVIRONMENT

In addition to the physical consequences to human beings of environmental deterioration, it is useful to consider what kind of environment they are best adapted to. What size groups does a person feel most comfortable in? How important is solitude for the well-being of the human psyche? Is the color green, which is known to have a soothing effect, an important component of the human environment? Have human beings evolved to feel most comfortable in a certain kind of environment, and, if so, can evolution rapidly adapt *Homo sapiens* to a new one? Such questions have been the subject of extensive speculation, but they are exceedingly difficult to answer. In theory, for instance, natural selection could change certain human characteristics dramatically in six to eight generations -- in only about 200 years (although this would involve a very large portion of the population's not reproducing in each generation). But other characteristics may be so ingrained in the human geneticdevelopmental system that they would be impossible to change without much longer periods of genetic readjustment, or the changes might even be so traumatic as to lead to extinction.

To give an analogy, one may, by selection, experimentally create a strain of fruit flies that is resistant to DDT in six to eight generations, presumably as a result of some minor changes in enzyme systems or behavior. It seems unlikely, however, that any number of generations of selection would produce a fruit fly able to fly with one wing; in fact, an attempt to produce such a change by artificial selection would probably lead to extinction of the experimental population.

Some biologists feel that humanity's evolutionary history has been such that the present environments to which people are being subjecte figuratively amount to

[211a] For a much more through the discussion of the subsidence, as well as of landslides, see H. W. Menard, *Geology, resources, and society*, chapter 14, and P. T. Flawn, *Environmental geology*.

flying with one wing. This general viewpoint has been expressed by three biologists at the University of Wisconsin, who believe that mankind's genetic endowment has been shaped by evolution to require "natural" surroundings for optimum mental health:

> Unique as we may think we are, we are nevertheless as likely to be genetically programmed to a natural habitat of clean air and a varied green landscape as any other mammal. To be relaxed and feel healthy usually means simply allowing our bodies to react in the way for which one hundred millions of years of evolution has equipped us. Physically and genetically, we appear best adapted to a tropical savanna, but as a cultural animal we utilize learned adaptations to cities and towns. For thousands of years we have tried in our houses to imitate not only the climate, but the setting of our evolutionary past: warm, humid air, green plants, and even animal companions. Today, if we can afford it, we may even build a greenhouse or swimming pool next to our living room, buy a place in the country, or at least take our children vacationing on the seashore. The specific physiological reactions to natural beauty and diversity, to the shapes and colors of nature (especially to green), to the motions and sounds of other animals, such as birds, we as yet do not

comprehend. But it is evident that nature in our daily life should be thought of as a part of the biological need. It cannot be neglected in the discussions of resource policy for man. [212]

There is little consensus among cultures, or even within our own culture, on what sort of an environment best provides an optimal quality of life. In addition, there is very little experimental evidence on how varying such factors as the density of the population, the level of noise, or the amount of green in the environment may alter human behavior.

It is known from the systematic observations of anthropologist Edward T. Hall that peoples of different cultures have different perceptions of "personal space." [213] It is not clear, however, how much such differences are attributable to the *perception* of crowding as opposed to *tolerance* of crowding. For instance, do the residents of Tokyo feel uncrowded at densities that might make residents of Los Angeles feel intolerably crowded, or are the Japanese somehow better able to tolerate the crowding, even though their perceptions of it may be essentially the same?

There is almost no information on the levels of crowding at which people feel most happy and comfortable and can perform various tasks with the greatest efficiency. It is not known whether high density during one part of the daily routine (at work, for example) coupled with low density at another (at home) would have the same effects as medium density throughout the day. It is not known exactly what role high density may play in mental health and the incidence of stress diseases [214] nor whether density alone can be a contributing cause to riots. People have many opinions about such questions, but there is little solid information on which to base conclusions.

Some experimental work on the effects of crowding on human beings has been done by psychologist Jonathan Freedman and his associates in collaboration with one of us. [215] In short-term experiments, no differences were found between crowded and uncrowded groups in performance of a series of tasks. When games were played that permitted competitive or cooperative strategies to be adopted, or when other measures of social interaction were used, the results were more interesting. In all-male groups a crowded situation produced significantly higher levels of competitiveness. In all-female groups the result was reversed; the women in crowded circumstances were more cooperative, while those in less crowded conditions were more competitive. In mixed groups (both sexes present) crowding had no detectable effect.

These results must be interpreted with much caution. They suggest that all-male juries should be avoided, as well as groups of men making world-shaking decisions in crowded rooms. But the results do not reveal much about the more general effects of crowding in human populations, except to reinforce the notion that human beings can adapt readily to what *a priori* might seem to be difficult conditions -- at least, as far as task-performance is concerned.

[213] *The hidden dimension*; see also Robert Sommer, *Personal space*.
[214] John Cassel, *Health consequences of population density and crowding*.
[215] P. R. Ehrlich and J. Freedman, *Population, crowding, and human behavior*; J. L. Freedman, *Crowding and behavior*.

Much of the discussion of effects of crowding on human beings has been based on extrapolation from the results of behaviorist John Calhoun's classic studies of crowded rats. [216] The assumption is sometimes made that the kinds of social and physical pathologies he observed in crowded rats will sooner or later turn up in populations of people if they become too crowded. What studies exist on human populations have provided conflicting or ambiguous results. The chief difficulty is to untangle density effects from other social factors such as poverty, unemployment, lack of education, and rates of migration. [217] Even if high density does lead to social pathology in people, it is clear that many other limiting factors would come into play before the human population grew to the point where density itself set a limit. After all, people living in the most crowded cities, such as Manhattan and Tokyo, have not shown social pathologies to a degree sufficient to halt population growth. If only one-fourth of the land surface of Earth were populated to the density of Tokyo, the world population would be about 600 billion people. Clearly, something besides density itself -- famine, plague, war -- will stop the growth of the human population long before that point is reached.

Due to the lack of data, we must resort to speculation in further discussion of the psychological and social effects of human crowding. In dealing with a high population density, the Japanese seem to have developed a variety of cultural devices to alleviate the stress. It has been suggested that their very formal and elaborate etiquette may be one mechanism for self-protection against the inevitable frictions of constant human encounter. The Japanese have been relatively crowded for a long time; by 1870 Japan had 82 people per square kilometer. Thus, a century ago, Japan had almost four times the population density of the United States today.

In contrast to the Japanese and the Europeans, who also have had high population densities for several generations, people from currently or recently lowdensity countries (such as the United States or Australia) are likely to have reputations of being informal and easygoing, or even bumptious and rude. The Japanese are famous for their interest in aesthetic values, which they demonstrate in their arts and their lovely gardens. They also successfully create an illusion of space where there is very little in their homes and buildings, a talent that possibly contributes much to domestic serenity.

People generally are unaware of the influence that population size and density have upon their ways of life and their perceptions of the world. After all, these factors usually do not change drastically in times on the order of a generation or less. When they do change rapidly, as they are today in many less developed countries, the result seems more likely to produce disruption than gradual social change. Around 1910 the United States had about half the number of people it has today. Society then differed from today's in ways that cannot be entirely explained by the processes of industrialization and urbanization or by such historical events as two world wars, a depression, and two "limited" wars. Such qualities as friendliness and neighborliness, once common in this country and generally esteemed, now seem to exist primarily in rural areas, small towns, and occasionally in enclaves in big cities. In myriad ways the lives of Americans have become more regulated and regimented, a trend that is at least partly due to population growth. Few would claim that such changes contribute positively to the quality of American life.

The Urban Environment

The deterioration of the U.S. environment, both physically and aesthetically, is most apparent in cities. The dehumanizing effect of life in the slums and ghettoes particularly, where there is little hope for improving conditions (Figure 10-11), have often been cited as causes contributing to urban rioting and disturbances. Crime rates usually reach their zenith in these neighborhoods. Such symptoms of general psychological maladjustment suggest that modern cities provide a less than ideal environment for human beings.

There seems to be abundant evidence that traditional cultural patterns break down in cities, and also that the high numbers of contacts with individuals not part of one's circle of regular social acquaintances may lead to

---

[216]Population density and social pathology.

[217]O. R. Galle, W. R. Gove, and V. M. McPherson, *Population density and pathology: What are the relationships for man?*

FIGURE 10-11
Attempts at urban renewal to provide housing for the poor are not always successful. This huge project in St. Louis was so badly designed that some buildings had been abandoned and were scheduled for demolition only fifteen years after they were built. (Photo by William A. Garnett.)

mental disturbance (defined here merely as behavior generally considered disturbed by the majority of the society). It is important to note that antisocial behavior and mental illness are found in all cultures, and that indeed the same disorders recognized by psychiatrists in the West are found even in primitive peoples. Therefore, it seems reasonably certain that lack of a natural environment (where *natural* refers to the sort of environment in which *Homo sapiens* evolved) is not the sole cause of such behavior. Nevertheless, that lack may well serve to aggravate the problems of people living in our most crowded, smoggy, and impersonal metropolises.

Crime rates are some 5 times as high in urban as in rural areas. Though some of this difference may be due to disparities in reporting, not all of it can be explained on this basis. Such factors as unemployment, poverty, and a poor social environment undoubtedly contribute, as well. Some studies have shown rates of violent crimes to be positively correlated with actual population densities in American cities. [218] As urban population densities have risen in the past generation, so have crime rates.

However, none of these studies show that crowding alone causes crime. Indeed, careful statistical studies show that density itself is not positively correlated with crime rates or other social pathologies. [219] Jay Forrester has suggested that the rate of migration into a city is more highly correlated with crime rates. [220] More recent work indicates that crowding *per se* is neither good nor bad but merely tends to intensify each individual's reaction to a given situation. [221] The only exception is that crowding may have a slight association with minor mental disturbances. [222]

The environmental deterioration of American cities is most obvious to the poor who live in them. For them, environmental deterioration has nothing to do with the disappearance of fish and wildlife in national forests or litter in campgrounds. Their concern is ghetto ecology, including the wildlife in their homes -- rats, mice, and cockroaches. Air pollution reaches its highest levels in city centers; here also are there most likely to be inadequate sewage and solid-waste disposal systems. Heat in winter is often insufficient, space is at a premium, crime rates and vandalism are high, food is often inadequate, medical care is poor at best, opportunities for recreation are virtually nil, schools are at their worst, and public transportation is expensive and inconvenient. In short, all the problems and disadvantages of cities are greatly intensified for the poor. This environmental syndrome is reflected by higher death rates among the poor (especially infant and child mortalities) than for the general population.

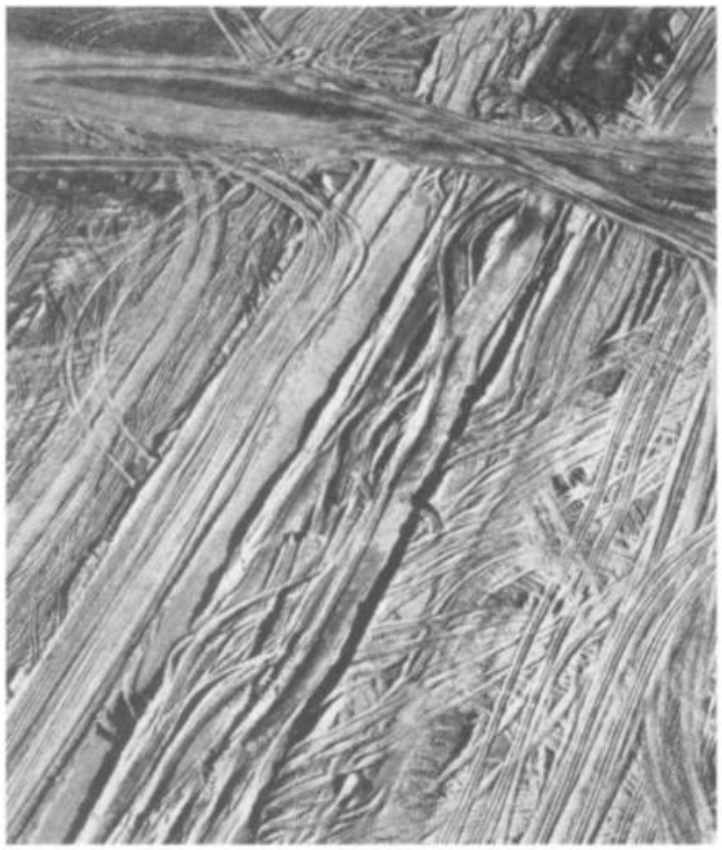

FIGURE 10-12
Many urban problems are largely the result of unplanned, haphazard development. Planning could avoid the serious problems of congestion, transportation, and destruction of valuable land that accompany urban sprawl, as exemplified here. Massproduction techniques are used to cover huge areas in the Los Angeles basin with houses in a few months. Upper left. Land cleared for building. Upper right. Foundations poured and lumber stacked neatly for each unit. Lower left. Siding and roofs in place. Lower right. The result. (Photos by William A. Garnett.)

Of course, many, if not most, of the present hazards and discomforts of city life could be eliminated or mitigated by more creative design of houses and neighhorhoods (Figure 10-12), by the development of alternative, less-polluting means of transportation, by finding solutions to the problems of racial minorities and the poor in general, and by more efficient and equitable forms of administration. If urban areas were planned and developed so people could live near their places of employment, many problems related to transportation would be alleviated, including congestion and pollution from automobiles. Making the vicinities of factories pleasantly habitable would present some problems but would result in considerable pollution abatement. Similarly, the social problems created by the separate existence both of suburban bedroom communities and city-center ghettoes might also be relieved. Of course, all of this requires vast infusions of time, imagination, and money, all of which are in short supply.

Aesthetic Considerations

Some destitute mountain folk from the Appalachians, who were moved to New York where jobs were available, promptly fled back to the mountains, preferring poverty

amid pleasant surroundings to life in such a horrible place. The aesthetic poverty of U.S. cities and suburbs has reached such a degree that most citizens are aware of it. Newspapers are replete with stories describing slums, ghettos, rats, trash, and garbage. This is one of the reasons why weekends and holidays invariably bring on a mass exodus from the cities. Unfortunately, frontier habits of thoughtless littering and defacement seem likely to reduce attractive rural areas and state and national parks to similar levels of ugliness.

Studies with young animals and indirect evidence from young children indicate that the richness of the sensory environment early in life influences the extent of later mental development. Sensory stimulation in young rats resulted in measurably larger brain sizes in adulthood than in their sensorily deprived litter-mates, and it affected their learning and problem-solving abilities as well. Children who have been exposed to a variety of sights, sounds, and experiences when they are very young may learn faster and later on be more likely to develop attitudes of inquiry and exploration.

Yet cities, once a rich source of varied sensory experiences, are becoming more monotonous and dismal. Modern urban development programs flatten blocks at a time -- blocks that once included a mixture of buildings of different ages and styles -- and then replace them with concrete monoliths that lack aesthetic quality. The variety of sounds, at least some of which were pleasing to hear, in smaller towns and on farms, is also coming to be replaced by an incessant din of traffic and construction.

A zoologist with an interest in environmental psychology, A. E. Parr of the American Museum of Natural History, has written that city children of a generation or two ago spent much of their time exploring and participating in the activities of the city, while today children are confined to dreary schoolrooms, their homes, and the local park. Poorer ones may play in the streets, and in this respect perhaps they are luckier. But many of today's city children are being deprived of firsthand knowledge about the city they live in and how the social organizations within it function, which creates a sort of alienation from their surroundings. At the same time their surroundings are becoming more and more monotonous and less attractive. Children's urges toward inquisitiveness, exploration, and ingenuity (qualities that will be desperately needed in the next generation) may thus be stifled outside the schools as well as in them. [223]

Suburbs are often better than the cities in aesthetic qualities and sensory stimulation, but not invariably so. Although the environment is usually more natural and includes trees and gardens, many suburbs tend to reduce everything to a common denominator. All the houses in a given area are similar, if not identical, and so are the gardens, parks, and shopping centers. Each modern real-estate development is generally inhabited by people of about the same age, educational level, type of employment, and economic status. There is not much opportunity for children to meet people whose points of view differ from their own or those of their parents. Although the children may be freer to explore in the suburbs than in the city, there is sometimes even less of interest to find there. The absence of men most of the time may result in an even greater alienation of youngsters (and wives as well) from the functioning society. Of course, television may compensate somewhat for the lack of sensory and social variety in children's lives, but it does not encourage inquisitiveness or offer opportunities for exploration, ingenuity, or direct experience. On the contrary, it may foster passiveness and a tendency to regard life as a spectator sport.

THE EPIDEMIOLOGICAL ENVIRONMENT

Today the population of *Homo sapiens* is the largest in the history of the species, it has the highest average density, and it contains a record number of undernourished and malnourished people. The population, or rather a small but important segment of it, is also unprecedentedly mobile. People are in continual motion around the globe, and they are able to move from continent to continent in hours. The potential for a worldwide epidemic (pandemic) has never been greater, but people's awareness of this threat has probably never been smaller. Contrary to popular belief, "medical science" has definitely not conquered epidemic disease, as recent experience with

influenza, cholera, typhoid, yellow fever, and Lassa fever have shown. [224]

The behavior of viruses is not completely understood, but it is known that the spontaneous development of highly lethal strains of human viruses and the invasion of humanity by extremely dangerous animal viruses are possible. It is also known that crowding increases the chances for development of a virus epidemic. Should, say, an especially virulent strain of flu appear, it is doubtful that the United States and other developed countries could produce enough vaccine fast enough to save most of their populations. Needless to say, the problem would be even more severe in the LDCs. Certainly, little effort could be made to save most of humanity. Consider, for example, the difficulty the United States had in coping with the mild Asian flu epidemic of 1968. It was not possible to manufacture enough vaccine to protect most of the population, and the influenza death rate in 1968 was more than 4 times as high as that of 1967. Only 613 deaths were attributed to flu, but society paid a high price for the disease in extra medical care and loss of working hours. That the number of deaths was not higher was due primarily to the relatively mild character of the virus, rather than to modern medicine. More recently, the swine flu fiasco of 1976-1977 certainly did not build confidence that public health machinery will be able to cope competently with future epidemic threats.

In 1967 an outbreak of a previously unknown disease occurred among a shipment of vervet monkeys that had been imported into laboratories in Marburg, Germany, and in Yugoslavia. This severe, hemorrhagic disease infected 25 laboratory workers who came into contact with the monkeys and their tissues. Seven of those people died. Five secondary infections occurred in individuals who came into contact with the blood of the original patients; all of those individuals survived. Humanity was extremely fortunate that the first infections of *Homo sapiens* by Marburg virus occurred around laboratories where the nature of the threat was quickly recognized, and the disease contained (it was not susceptible to antibiotics). If it had escaped into the human population at large, and if the disease had retained its virulence as it passed from person to person, an epidemic resulting in hundreds of millions or even billions of deaths might have occurred. Among well-fed laboratory workers with expert medical care, 7 out of 30 patients died. [225] Among hungry people with little or no medical care, mortality would be much higher. The infected monkeys passed through London airport in transit to the laboratories. If the virus had infected airport personnel, it could have spread around the world before anyone realized what was happening. In addition, it is hardly reassuring that infection of laboratory workers with viruses is a rather common occurrence, and the potential virulence of possible "escapees" from labs is increasing. [226]

The highly mechanized society of the United States is also extremely vulnerable to disruption by such events as power failures, floods, and snowstorms. What would happen if the nation were confronted with an epidemic that kept masses of sick people from work and caused the uninfected to stay home or flee the cities because of their fear of infection? This might slow or even stop the spread of the disease, but hunger, cold (in the winter), and many other problems would soon develop as the services of society ceased to operate. Almost total breakdown has been known to occur in much less complex societies than the U.S. in the face of the black death -- breakdown that occurred among people far more accustomed to a short life, hardship, disease,

and death than the population of the Western world today. [227] The panic may well be imagined if Americans were to discover that "modern medical science" either had no cure for a disease of epidemic proportions, or had insufficient doses of the cure for everyone. The disease itself would almost certainly impede the application of any ameliorating

measures. Distribution of vaccines, for instance, would be difficult if airlines, trains, and trucks were not running.

In many parts of the world, public-health conditions are developing that have a high potential for disaster. The rats that live on stored grain in India have renewed the specter of a major outbreak of bubonic plague. Nitrate pollution of water is creating conditions in which dangerous soil organisms are brought into contact with human beings for the first time. The organism that has recently caused cases of a fatal meningitis has been identified as a soil-dwelling amoeba. [228] It may be just the first of many such agents to appear seemingly from nowhere.

Irrigation projects in the tropics and subtropics around the world are spreading the conditions that promote the parasitic disease *schistosomiasis (bilharzia)*, which, together with malaria, is one of the two most prevalent serious diseases on Earth. [229] The broadcast use of chemotherapy and antibiotics has created a serious medical problem through the introduction of resistance in bacteria and other parasites. Modification of the climate would also inevitably influence disease patterns; for example, the length of time viruses remain infectious is in part a function of humidity. A trend toward drying would encourage some, whereas others would thrive in increased moisture. It is suspected, in addition, that weather changes can trigger epidemics. [230]

As if the threat of a natural pandemic were not gruesome enough, there is always the threat of biological warfare or of an accidental escape of lethal agents from a biological warfare laboratory or, conceivably, from a laboratory engaged in genetic engineering experiments (see material on recombinant DNA research in Chapter 14). Although most laypeople have long been afraid of thermonuclear war, they are just beginning to grasp the colossal hazard posed by

chemical and biological warfare (CBW). Any country with one or two well-trained microbiologists and even a modest budget can build its own biological doomsday weapons. Constructing lethal viruses against which there is little or no resistance in human populations can easily be done in theory; it may already have been done in practice. There were at one time rumors of the development by the American CBW establishment of a pneumonic rabies, one that, instead of being transmitted by bite, is transmitted in the same way as the common cold: from person to person via exhaled droplets. This is certainly possible, since under special conditions (such as those that sometimes occur in caves full of rabid rats) rabies appears to have been transmitted through the air. Such a disease would be a disastrously effective weapon if it were transmitted by infected individuals before symptoms appear, since once they do appear, rabies is (with one notable recent exception) 100 percent fatal. Other possibilities for lethal agents are many -- for example, anthrax, which even in its "natural" state can be transmitted by contaminated aerosols, plague, tularemia, Q-fever, and encephalitis, to name a few [231] -- disseminated in their natural forms or in the form of special "hot" strains that are drug-resistant or superlethal. Besides direct assaults on human beings, overt or covert attacks on a nation's food supply might be made by introducing plant diseases. The more crowded a population is, and the smaller its per-capita food supplies, the better a target it would be for a biological warfare attack.

Why would nations develop such weapons? For the same reason they develop others. They hope to immunize or otherwise protect their own populations and thus avoid a biological backlash. These weapons have a special appeal for small and poor powers, which see themselves threatened by larger, richer ones and which lack the funds or the expertise to develop nuclear weapons. [232]

Chemical-biological weapons may never be used, but that does not rule out the possibility of an accident. Virus laboratories, especially, are notoriously unsafe. By 1967, some 2700 laboratory workers had become accidentally infected with viruses transmitted by insects, and 107 had died. [233] Their deaths were caused by just one group

of viruses. Fatal accidents occur in laboratories where work is done on other kinds of viruses, as well as other microorganisms. The inability of government CBW agencies to avoid accidents was made clear by the Skull Valley, Utah, CBW disaster of 1968, in which many thousands of sheep were poisoned when a chemical agent "escaped," [234] and by the possible escape of Venezuelan Equine Encephalitis from the Dugway, Utah, proving ground in 1967. Congressman

Richard D. McCarthy of New York announced in 1969 that CBW agents were being transported around the country in small containers *on commercial airliners!*

In 1969, President Nixon announced the unilateral renunciation by the United States of the use of biological warfare, even in retaliation. [235] He directed that the stocks of biological agents be destroyed and that further work on defenses against biological weapons be transferred from the Department of Defense to the Department of Health, Education and Welfare. Destruction of U.S. biological warfare materials was systematically carried out in 1970 and 1971, although in 1975 it was discovered that the Central Intelligence Agency had not destroyed some toxins in its possession.

Some level of research might be continuing clandestinely in the United States (although the possibility seems remote), and it would be a simple matter for a future administration quickly to reestablish biological warfare capability. Indeed, with the rapidly increasing ability of biologists to manipulate the genetics of microorganisms, the possibilities for creating deadly agents seem endless. [236] Furthermore, there is little sign that the U.S. action has led to the end of work on biological weapons elsewhere. Biological warfare laboratories are potential sources of a man-made "solution" to the population explosion. It is essential that some way be found to block all further work on biological weapons -the risk for humanity is simply too great.

It should be clear now that humanity is creating an enormous array of hazards that directly threaten the health and welfare of all people. Unfortunately many of these hazards are poorly understood, and many undoubtedly remain unrecognized at present. The next chapter shows that the level of *indirect* threats to human welfare is just as high and the level of understanding just as low.

(Cowell, E. B. 1976. Oil pollution of the sea. In R. Johnston, ed., *Marine pollution*, pp. 353-401. Concludes that added cancer risks from oil in seafoods must be very low, and that ecosystemic effects are likely to be much less than those of other pollutants such as heavy metals and chlorinated hydrocarbons.

Craig, R. E. 1976. Dispersion in estuaries and inshore waters. In R. Johnston , ed., *Marine pollution*, pp. 159-183. A mathematical treatment of a topic key to the appraisal of the pollution situations.

Crossland, J., and V. Brodine. 1973. "Drinking water". *Environment*, vol. 15, no. 3, pp. 11-19. Excellent treatment of chemical, bacterial, and viral pollution of drinking-water supplies, including problems and limitations of chlorination.

Crow, J. F. 1968. Chemical risk to future generations. *Scientist and Citizen*, June/July, pp. 113-117. A distinguished geneticist considers the risks of chemical mutagenicity may be as serious as those from radiation.

Curley, A., and R. Kembrough. 1969. Chlorinated hydrocarbon insecticides in plasma and milk of pregnant and lactating women. *Archives of Environmental Health*, vol. 18, pp. 156-164. Showed an average of 0.06 to 0.08 parts per million DDT-R in first three months after delivery, with a range of 0.04 to 0.16 parts per million.

Curley, A.; V. Sedlak; E. Girling; R. Hawk; W. Barthel; P. Pierce; and W. Likosky . 1971. Organic mercury identified as the cause of poisoning in humans and hogs. *Science*, vol. 172, pp. 65-66 (April 2).

Dale, W. E.; M. F. Copeland; and W. J. Hayes, Jr. 1965. "Chlorinated insecticides in the body fat of people in India". *Bulletin of World Health Organization*, vol. 33, pp. 471-477. Source of Indian data.

David, O.; J. Clark; and K. Voeller. 1972. Lead and hyperactivity. *Lancet*, October, pp. 900-903.

Deichmann, W. B.; W. E. MacDonald; and D. A. Cubit. 1971. DDT tissue retention: Sudden rise induced by the addition of aldrin to a fixed DDT intake. *Science*, vol. 172, pp. 275-276 (April 16). A disturbing synergism.

Deitz, V. R., ed. 1975. *Removal of trace contaminants from the air*. American Chemical Society, Washington, D.C. Technical treatise covering a wide variety of contaminants from combustion products to pesticides.

Dickson, E. M. 1972. Mercury and lead in the Greenland ice sheet: A reexamination of the data. *Science*, vol. 177, pp. 536-538 (August 11).

Dixon, B. 1972. "Typhoid bacilli learn a new trick". *New Scientist*, vol. 55, pp. 571-580. Some strains of this deadly bacterium have become resistant to the "drug of choice," chloramphenicol.

Doll, Richard. 1974. "Smoking, lung cancer, and Occam's razor". *New Scientist*, vol. 63, February 21, pp. 463-467. A persuasive rebuttal to Phillip Burch's position that smoking doesn't actually cause lung cancer. Doll explains why most authorities believe there is a causal relationship.

Dubos, René. 1965. *Man adapting*. Yale University Press, New Haven. Deals with many of the problems covered in this chapter.

Duggan, R. E., and J. R. Weatherwax. 1967. Dietary intake of pesticide chemicals. *Science*, vol. 157, pp. 1006-1010 (September 1). Highest residues in meat, fish, and poultry.

Edelson, Edward. 1973. "Food laws should be even tougher". *New Scientist*, vol. 57, pp. 315-316. Brief overview of Delaney clause controversy.

Edmondson, W. T. 1975. Fresh water pollution. In *Environment*, William W. Murdoch, ed. Useful survey.

Edsall, J. T. 1976. "Toxicity of plutonium and some other actinides". *Bulletin of the Atomic Scientists*, vol. 32, no. 7 (September), pp. 27-37. Good review article, citing several kinds of evidence for the view that plutonium is more dangerous than present standards imply.

Edvarson, K. 1975. "Radioecological effects of nuclear warfare". *Ambio*, vol. 4, no. 5/ 6, pp. 209-210. Estimates of radiation doses to people and the associated delayed casualties from hemispheric fallout after a large nuclear war.

Ehrlich, Paul R., and J. L. Freedman. 1971. "Population, crowding, and human behaviour". *New Scientist*, April 1. General discussion, reporting results of first experimental work on crowding in human beings.

Ehrlich, Paul R.; John P. Holdren; and Richard W. Holm, eds. 1971. Man and the ecosphere. W. H. Freeman and Company, San Francisco. Important papers from *Scientific American*, with critical commentaries.

Ehrlich, Paul R.; Richard W. Holm; and I. L. Brown. 1976. *Biology and society*. McGraw-Hill, New York. Contains a lay overview of molecular genetics and also of the biology of various environmental problems.

Ehrlich, Paul R.; R. W. Holm; and D. R. Parnell. 1974. *The process of evolution*. 2d ed. McGraw-Hill, New York. See especially the discussion of chromosomal alterations which in the present text are included under the rubric mutation.

Eisenbud, Merril. 1973. *Environmental radioactivity*, 2d ed. Wiley, New York. A wide-ranging introduction with an extensive bibliography. Includes details of techniques for computing maximum permissible concentrations and doses by various pathways.

Epstein, S. S. 1973. The Delaney amendment. *Ecologist*, vol. 3, pp. 424-431. A spirited defense of the Delaney clause by a distinguished cancer researcher.

-----. 1974. Environmental determinants of human cancer. *Cancer Research*, vol. 34, pp. 2425-2435. A key review article.

-----, and D. Hattis. 1975. Pollution and human health. In *Environment*, William W. Murdoch, ed. Good introduction to the epidemiological aspects of pollution.

-----, A. Hollaender, J. Lederberg, M. Legator, H. Richardson, and H. H. Wolff . 1969. Wisdom of cyclamate ban. *Science*, vol. 166 p. 1575 (December 26). Useful discussion of why the ban should be supported.

Fiserova-Bergerova, V.; J. L. Radomski; J. E. Davis; and J. H. Davis. 1967. Levels of chlorinated hydrocarbon pesticides in human tissues. *Industrial Medicine and Surgery*, vol. 36, pp. 65-70.

Flawn, P. T. 1970. *Environmental geology*. Harper & Row, New York. Excellent material on earthquakes, subsidence, man as a geological agent, and so forth.

Foote, R. S. 1972. Mercury-vapor concentrations inside buildings. *Science*, vol. 177, pp. 513-514 (August 11).

Forrester, Jay W. 1971. "Counterintuitive behavior of social systems". *Technology, Review*, vol. 73, no. 3, pp. 52-68. Preliminary report of "Limits to Growth" study, with discussion of the relation of population density to crime rates.

Franklin, B. A. 1976. "A crippler called Kepone". *This World* (San Francisco Examiner and Chronicle), February 15.

Freedman, J. L. 1975. *Crowding and behavior*. W. H. Freeman and Company, San Francisco. Review by a psychologist who is one of the pioneers in research on crowding.

French, J.; G. Lourimore; W. Nelson; J. Finklea; T. English; and M. Hertz . 1973. The effect on sulfur dioxide and suspended sulfates on acute respiratory disease. *Archives of Environmental Health*, vol. 27, pp. 129-133.

Friedman, I., and N. Peterson. 1971. Fossil fuels as a source of mercury pollution. *Science*, vol. 172, pp. 1027-1028 (June 4). Mercury pollution from fossil fuels is shown to be comparable to that from industrial waste.

Fuller, J. G. 1974. *Fever! The hunt for a new killer virus*. Ballantine, New York. Popular account of Lassa fever.

Galle, O. R.; W. R. Gove; and V. M. McPherson. 1972. Population density and pathology: What we the relationships for man? *Science*, vol. 176, pp. 23-30 (April 7). Untangling variables is difficult.

Galle, O. R.; J. D. McCarthy; and W. Gove. 1974. *Population density and pathology*. Paper presented at the annual meeting of the Population Association of America in New York, 1974. No positive correlation found between crowding and alcoholism, suicide, or homicide -and a negative one with the latter two.

Galston, A. W. 1971. "Some implications of the widespread use of herbicides". *BioScience*, vol. 21, pp. 891-892, See also papers by Johnson and by Westing in the same issue.

Gamberale, Francesco. 1975. Behavioral toxicology: A new field of job health research. *Ambio*, vol. 4, no. 1, pp. 43-46. Performance may be affected by exposure to certain substances, and irreversible effects on the central nervous system are possible.

Garrels, R. M.; F. T. Mackenzie; and C. Hunt. 1975. *Chemical cycles and the global environment*. Kaufmann, Los Altos, Calif. Contains useful information on flows and toxicity of trace metals.

Gaspar, P. P. 1975. Sulfur in the atmosphere. In *Sulfur in the environment, Missouri Botanical Garden*. St. Louis. Excellent survey of sulfur's reactions in the atmosphere.

German, James, ed. 1974. *Chromosomes and cancer*. Wiley, New York. A collection of technical papers on the changes associated with cancer in the gene-bearing organelles of the cell. See especially the article by Burnet, "The biology of cancer".

Gilbert, R. G.; R. C. Rice; H. Bouwer, C. P. Gerba; C. Wallis; and J. L. Melnick . 1976. Waste water renovation and reuse: Virus removal by soil filtration. *Science*, vol. 192, pp. 1004-1005 (June 4). Encouraging evidence that human viral pathogens are effectively removed by filtration of viruses through soil.

Gilder, S. S. B. 1973. "The passive smoker". *Canadian Medical Association Journa* vol. 109, no. 11, pp. 1084-1089 (December 1). Shows nonsmokers in a room with smokers reach a CO blood level equal to that of smokers smoking I cigarette per hour. Also correlates children's respiratory illness with parents' smoking.

Gilfillan, S. C. 1965. "Lead poisoning and the fall of Rome". *Journal of Occupational Medicine*, February, pp. 53-60. Detailed historical case study. Fascinating.

Gofman, J. W. 1975. *The cancer hazard from inhaled plutonium*. Committee for Nuclear Responsibility, Dublin, Calif.

----- and A. R. Tamplin. 1971. *Poisoned power*. Rodale, Emmaus, Pa. Scientists from the Lawrence Radiation Laboratory present their case on radiation and the hazards of nuclear power.

Goldberg, E. D. 1965. In *Chemical oceanography*, J. P. Riley and G. Skirrow , eds. Academic Press, New York. pp. 163-196.

-----, and K. K. Bertine. 1975. Marine pollution. In *Environment*, William W. Murdoch, ed. Excellent material on trace metals.

Goldsmith, J. R., and A. I. Hexter. 1967. Respiratory exposures to lead: Epidemiological and experimental dose-response relationship. *Science*, vol. 158, pp. 132-134 (October 6).

Goldwater, C. J.; A. J. Rosso; and M. Kleinfeld. 1965. Bladder tumours in a coal tar dye plant. *Archives of Environmental Health*, vol. 11, pp. 814-817. High rates of induction recorded.

Gordon, J. E., and N. S. Scrimshaw. 1973. "Cholera morbus revisited". *International Journal of Environmental Studies*, vol. 4, pp. 291298. Good overview of cholera.

Grant, Neville. 1971. Mercury in man. *Environment*, vol. 13, no. 4, pp. 8-15. Useful introductory article.

Greenberg, D. S. 1975. Stalemate in cancer treatment. *Environment*, April/May, pp. 19-20, 25. (Reprinted from Science and Government Report, Dec 1, 1974.) Describes in statistical detail the failure of the War on Cancer boondoggle.

Groth, Edward III. 1975. Fluoride pollution. *Environment*, vol. 17, no. 3, pp. 29-38. Very comprehensive and even-handed review.

Gruener, N., and R. Toeplitz. 1975. "The effect of changes in nitrate concentration in drinking water on methemoglobin levels in infants". *International Journal of Environmental Studies*, vol. 7, pp. 161-163.

Hall, E. T. 1966. *The hidden dimension*. Doubleday, Garden City, N.Y. Basic source on human use of personal space.

Hamilton, D. H., and R. L. Meeham. 1971. Ground rupture in the Baldwin Hills. *Science*, vol. 172, pp. 333-344 (April 23). Dam failure traced to fluid injection in nearby oil fields.

Hammond, E. C., and D. Horn. 1958. "Smoking and death rates: Report on forty-four months of follow-up of 187,783 men: pt. 1, Total mortality; pt. 2, Death rates by cause". *Journal of the American Medical Association*, vol. 166, pp. 1159-1172, 1294-1308. Huge epidemiological study showing clear relationship of smoking to coronary discease, lung cancer, and other cancers.

Hammons, A. S., and J. E. Huff. 1974. "Asbestos. World concern, involvement, and culpability". *International Journal of Environmental Studies*, vol. 6, pp. 247-252. Review of worldwide exposure.

Hanson, R. P.; S. E. Sulkin; E. L. Buescher; W. McD. Hammon; R. W. McKinney ; and T. H. Work. 1967. Arbovirus infections of laboratory workers. *Science*, vol. 158, pp. 1283-1286 (December 8). Describes incidence of laboratory accidents with arthropod-borne viruses.

Harris, R. J. C. 1970. "Cancer and the environment". *International Journal of Environmental Studies*, vol. 1, pp. 59-65. See especially sections on cultural cancers. Useful bibliography.

Hayes, W. J., Jr.; W. E. Dale; and C. I. Perkle. 1971. Evidence of safety of long-term high, oral doses of DDT for man. *Archives of Environmental Health*, vol. 22, pp. 119-135. Short-term study showing the undisputed lack of acute toxicity of DDT; it does not speak to human carcinogenesis or other long-term safety.

Hayes, W. J., Jr.; W. F. Durham; and C. Cueto. 1956. "The effects of known repeated oral doses of chlorophenothane (DDT) in man". *Journal of the American Medical Association*, vol. 162, pp. 890-897. Poorly designed study purporting to show DDT harmless to humans.

Healy, J. H.; W. W. Rubey; D. T. Griggs; and C. B. Raleigh. 1968. The Denver earthquakes. *Science*, vol. 161, pp. 1301-1310 (September 27). Injection of fluid wastes near Denver triggered earthquakes.

Hernberg, S.; J. Nikkanen; G. Mellin; and H. Lilius. 1970. δ-Aminolevulinic acid dehydrase as a measure of lead exposure. *Archives of Environmental Health*, vol. 21, pp. 140-145.

Hexter, A. C., and J. R. Goldsmith. 1971. "Carbon monoxide: Association of community air pollution with mortality". *Science*, vol. 172, pp. 265-267 (April 16). One of a relatively few major community studies relating air pollution to higher mortality.

Hiatt, V., and J. E. Huff. 1975. "The environmental impact of cadmium: An overview". *International Journal of Environmental Studies*, vol. 7, no. 4, pp. 277-285. Splendid review article.

Hinds, W. C., and M. W. First. 1975. "Concentrations of nicotine and tobacco smoke in public places". *New England Journal of Medicine*, vol. 292, no. 16, pp. 844-845 (April 17).

Hirschhorn, N., and W. B. Greenough, III. 1971. "Cholera". *Scientific American*, August. Map of recent pandemic, details on treatment, toxin, etc.

Hirst, Eric. 1973. "The energy cost of pollution control". *Environment*, vol. 15, no. 8, pp. 37-44. Indicates that control of air pollution, water pollution, solid waste, and thermal pollution to the extent and with the technologies envisioned in the early 1970s would use not more than a few percent of the United States energy budget at that time.

Hoffman, W. S.; W. I. Fishbein; and M. B. Andelman. 1964. The pesticide content of human fat tissue. *Archives of Environmental Health*, vol. 9, pp. 387-394. Discusses establishment of equilibrium concentrations of DDT.

Holdren, John P., and Paul R. Ehrlich, eds. 1971. *Global ecology*. Harcourt Brace Jovanovich, New York. Includes basic papers on several classes of environmental hazards.

Holmberg, B. 1975. "Biological aspects of chemical and biological weapons". *Ambio*, vol. 4, no. 5, pp. 211-215. Excellent survey of effects on humans and the environment.

-----. 1975. "The inhuman factor". *Ambio* vol. 4, no. 1, pp. 1-5. An overview of occupational health with suggestions for improving it.

Hoover, R., and J. F. Fraumeni, Jr. 1975. *Cancer mortality in U.S. counties with chemical industries Environmental Research* vol. 9, pp. 196-207. High mortality is associated with presence of chemical industries.

Hudson, H. E., and F. W. Gilcreas, 1976. "Health and economic aspects of water hardness and corrosiveness". *Journal of the American Waterworks Association*, vol. 68, pp. 201-204. Mortality rate from cardiovascular disease is 24 percent higher in communities with low total water hardness than in communities with high hardness.

Hueper, W. C. 1972. "Environmental cancer hazards". *Journal of Occupational Medicine*, vol. 14, pp. 149-153. Details on occupational carcinogenesis.

Hurn, R. W., ed. *Approaches to automotive-emissions control*. American Chemical Society, Washington, D.C. Detailed and technical.

Iltis, H. H.; O. L. Loucks; and P. Andrews. 1970. "Criteria for an optimum human environment". *Bulletin of the Atomic Scientists*, vol. 26, no. 1,

pp. 2-6. Discusses some of the less obvious requisites of human existence. Reprinted in Holdren and Ehrlich, Global ecology.

Innes, J. R. M.; B. M. Ullard, M. G. Valerir, L. Petrucelli; L. Fishbein; E. R. Hart ; A. J. Pallotta; R. R. Bates; H. L. Falk; J. J. Gart; M. Klein; I. Mitchell; and J. Peters. 1969. "Bioassay of pesticides and industrial chemicals for tumorigenicity in mice: a preliminary note". *Journal of the National Cancer Institute*, vol. 42, no. 6, pp. 1101-1114. Study of cancer induction in mice by a variety of chemicals, including DDT and several other pesticides.

Jahns, Richard H. 1968. "Geological jeopardy". *Texas Quarterly*, vol. 11, no. 2, pp. 69-83. (Reprinted in Holdren and Ehrlich, Global ecology.) A survey of geologic environmental hazards.

Jaworowski, Z. 1968. "Stable lead in fossil ice and bones". *Nature*, vol. 217, pp. 152-153.

Joensu, O. 1971. "Fossil fuels as a source of mercury pollution". *Science*, vol. 172, pp. 1027-1028 (June 4). Suggests a mean value of I part per million for average mercury content of coals worldwide.

Johnston, R. 1976. Mechanisms and problems of marine pollution in relation to commercial fisheries. In R. Johnston, ed., *Marine pollution*, pp. 3-156. Covers a vast range of topics--see especially material on North Sea oil and gas operations.

-----, ed. 1976. *Marine pollution*. Academic Press, New York. Up to date and comprehensive.

Jones, R. M., and R. Fagan, 1975. *Carboxyhemoglobin in nonsmokers: A mathematical model. Archives of Environmental Health*, vol. 30, no. 4, pp. 184-189.

Kagawa, J., and T. Toyama. 1975. "Photochemical air pollution". *Archives of Environmental Health*, vol. 30, pp. 117-122. Relates ambient concentrations of oxidants to physiological effects.

Kane, D. N. 1976. "Bad air for children", *Environment*, vol. 18, no. 9 (November), pp. 26-34. On children's special sensitivity to air pollution.

Kay, Kingsley. 1974. "Occupational cancer risks for pesticide workers". *Environmental Research*, vol 7, pp. 243-271. A thorough review. Bibliography covers 175 papers.

Kermode, G. O. 1972. "Food additives". *Scientific American*, March. A general survey of the types and uses of additives (excluding those given to live animals).

Kier, L. D.; E. Yamasaki; and B. N. Ames. 1974. "Detection of mutagenic activity in cigarette smoke condensates". *Proceedings of the National Academy of Sciences*, vol. 71, pp. 4159-4163. Ames test detects mutagenic activity in condensate and several fractions thereof; shows great promise for further investigations.

Kissling, R. E.; R. Q. Robinson; F. A. Murphy; and S. G. Whitfield. 1968. "Agent of disease contracted from green monkeys". *Science*, vol. 160, pp. 888-890 (February 20). Source on Marburgvirus.

Knox, J. F.; S. Holmes; R. Doll; and I. D. Hill. 1968. "Mortality from lung cancer and other causes among workers in an asbestos textile factory". *British Journal of Industrial Medicine*, vol. 25, pp. 293303. Occupational lung cancers caused by asbestos.

Knudson, A. G. 1973. "Mutation and human cancer". *Advances in Cancer Research*, vol. 17, pp. 317-352. Presents two-or-more-mutationalstep models of carcinogenesis in which, in hereditary disposition to cancer, the first step occurs before the egg is fertilized (that is, it is mutation-inherited from a parent).

Kochny, E. L, ed. 1973. "Trace elements in the environment". *American Chemical Society*, Washington, D.C. Nine chapters covering the main metals of health concern plus various dusts and aerosols.

Kraun, G. F.; L. J. McCabe; and J. M. Hughes, 1976. "Waterborne disease outbreaks in the U.S.: 1971 through 1974". *Journal of the American Waterworks Association*, vol. 68, pp. 420-424. Also includes discussion of historical trends.

Kryter, K. D. 1970. *The effects of noise on man*. Academic Press, New York. Useful for detailed information.

Kuratsune, M., et al. 1972. Epidemiological study of Yusho, a poisoning caused by ingestion of rice oil contaminated with a commercial brand of polychlorinated biphenyls. *Environmental health perspectives*, experimental issue no. 1, April.

Kyllonen, R. L. 1967. "Crime rate vs. population density in United States cities: A model". *Yearbook of the Society for General Systems Research*, vol. 12, pp. 137-145.

La F. M. Force; F. H. Bumford; J. C. Feeley; S. L. Stokes; and D. B. Snow . 1969. "Epidemiologic study of a fatal case of inhalation anthrax". *Archives of Environmental Health*, vol. 18, pp. 798-805. This deadly disease can be transmitted through the air.

Langer, W. L. 1964. "The black death". *Scientific American*, February. See especially psychosocial effects.

Lave, L., and E. Seskin. 1970. "Air pollution and human health". *Science*, vol. 169, pp. 723-733 (August 21). Good review of the evidence as of 1970. Estimates that a 50 percent reduction in air pollution would save 2 billion dollars in health care costs annually in the U.S.

Lave, L. B., and L. P. Silverman. 1976. "Economic costs of energy-related environmental pollution". In *Annual review of energy*, J. Hollander and M. Simmons, ods., vol. 1, Annual Reviews Inc., Palo Alto, Calif. Good survey of kinds of economic costs of pollution and methods of estimating them.

Laws, E. R., Jr.; A. Curley; and E. F. Biros. 1967. "Men with intensive occupational exposure to DDT". *Archives of Environmental Health*, vol. 15, pp. 766-775. This study tends to indicate little or no toxicity of DDT to adults during periods of a decade or more. It says nothing about the

effects of exposure during longer stretches, especially when exposure begins before birth. Information on the causes of death of men who have worked for chlorinated hydrocarbon manufacturers would be of greater interest on the subject of adult toxicity than this sort of study.

Laws, E. R.; W. C. Maddrey; A. Curley; and V. W. Burse. 1973. "Long-term occupational exposure to DDT". *Archives of Environmental Health*, vol. 27, pp. 318-321. Thirty-five men heavily exposed to DDT for an average of 25 years did not show liver disease.

Lederberg, J. 1968. "Swift biological advance can be bent to genocide". *Washington Post*, August 17. A distinguished molecular biologist speculates on biological warfare possibilities.

-----. 1970, "Yellow fever is still a menace". *San Francisco Sunday Examiner and Chronicle*, March 22. The threat to Asia seems especially severe.

-----. 1971. "Biological warfare: A global threat". *American Scientist*, vol. 59, pp. 195-197. An overview dealing also with the potential for natural epidemics.

Lee, A. M., and J. F. Fraumeni, Jr. 1969. "Arsenic and respiratory cancer in man: An occupational study". *Journal of the National Cancer Institute*, Vol. 42, pp. 1045-1052. Supports hypothesis that inhaled arsenic produces cancers of respiratory system, but other concomitant factors such as high concentrations of SO2 cannot be ruled out.

Lees, L., et al. 1972. "Smog: A report to the people". Ward Ritchie, Los Angeles.

Levinson, C. 1975. "The malevolent workplace". *Ambio*, vol. 4, no. 1, pp. 24-29. Survey of hazardous conditions and lax enforcement of standards around the world. Especially fine discussion of vinyl chloride.

Lewin, R. 1976. "Bacteria to be used to detect cancer-causing chemicals". *New Scientist*, January 22, p. 179. An excellent brief summary of the Ames screen.

-----. 1976. "Cancer hazards in the environment". *New Scientist*, January 22, pp. 168-169.

Lijinsky, W. 1973. "Nitrites in foods". *Science*, vol. 182, pp. 1194-1196 (December 21). Supports Schuck and Wellford, Botulism and nitrites.

-----. 1976. "Health problems associated with nitrites and nitrosamines". *Ambio*, vol. 5, no. 2, pp. 67-72. Good summary of chemistry and carcinogenic potential of nitrites used in processing of meat and fish.

-----, and S. S. Epstein. 1970. "Nitrosamines as environmental carcinogens". *Nature*, vol. 225, pp. 21-23. Suggests that cancers might be caused by nitrosamines formed in digestive tract from ingested nitrites and secondary amines.

Likosky, W. 1971. "Organic mercury identified as the cause of poisoning in humans and hogs". *Science*, vol. 172, pp. 65-66 (April 2). Ingestion of grain treated with organic mercury fungicides.

-----. 1977. "How nitrosamines cause cancer". *New Scientist*, January 27, pp. 216-217. Tells how altering molecular structure helps in understanding carcinogenetic activity.

Love, S. 1975. "An idea in need of rethinking: the flush toilet". *Smithsonian*, May, pp. 61-66.

Lowrance, W. W. 1976. "Of acceptable risk". Kaufmann, Los Altos, Calif. An interesting exploration of the concepts of risk, safety, and acceptability, with instructive examples.

Lumsden, M. 1975. Conventional" war and human ecology. *Ambio*, vol. 4, no. 5-6, pp. 223-228. Discussion of effects of World War II and Vietnam war on urban and rural environments.

MacDonald, G. J. F. 1969. "The modification of the planet Earth by man". *Technology Review*, vol. 72, no. 1, pp. 26-35. See especially the section on man-made earthquakes.

Magee, P. 1971. "Toxicity of nitrosamines: Their possible human health hazards". *Food and Cosmetics Toxicology*, vol. 9, pp. 207-218. Concludes hazard is difficult to assess.

-----. 1973. "Nitrosamines: Ubiquitous carcinogens?" *New Scientist*, August 25, pp. 432-434. Semipopular review, no bibliography.

Maltoni, Cesare. 1975. "The value of predictive experimental bioassays in occupational and environmental carcinogenesis--an example: vinyl chloride". *Ambio*, vol. 4, no. 1, pp. 18-23. Underscores the need for screening industrial compounds before they go into widespread use.

Martell, E. A. 1974. "Radioactivity of tobacco trichomes and insoluble cigarette particles". *Nature*, vol. 249, pp. 215-217. Shows that radioactive polonium taken up from the environment by tobacco plants shows up in smoke from cigarettes.

-----. 1975. "Tobacco radioactivity and cancer in smokers". *American Scientist*, vol. 63, no. 4, pp. 404-412. Argues that mechanism by which cigarette smoke causes cancer and arteriosclerosis is radioactivity taken up by the tobacco plant.

Marx, J. L. 1974. "Drinking water: Another source of carcinogens?" *Science*, vol. 186, pp. 809-811 (November 29).

Mason, T. J., and F. N. McKay. 1974. *U.S. cancer mortality by county: 1950-1969*. Department of Health, Education and Welfare, Washington, D.C., publication NIH 74-615.

Masters, G. M. 1974. *Introduction to environmental science and technology*. Wiley, New York. Good introductory text, with concise coverage of population, food, energy, and pollution control.

Maugh, T. H. 1973. "Trace elements: A growing appreciation of their effects on man". *Science*, vol. 181, pp. 253-254 (July 20). Excellent short overview.

-----. 1974. "Chemical carcinogenesis: A long-neglected field blossoms". *Science*, vol. 183, pp. 940-944 (March 8). An informative review by a science journalist.

McCann, J., and B. N. Ames. 1976. "Detection of carcinogens as mutagens in the Salmonella/microsome test: Assay of 300 chemicals--discussion". *Proceedings of the National Academy of Sciences*, vol. 73, pp. 950-954. Of 175 carcinogens, 157 (90 percent) were mutagenic. Discusses evidence that both chemical carcinogens and radiation cause cancer by damaging DNA.

McCann, J.; E. Choi; E. Yamasaki; and B. N. Ames. 1975. "Detection of carcinogens as mutagens in the Salmonella/microsome test: Assay of 300 chemicals". *Proceedings of the National Academy of Sciences*, vol. 72, pp. 5135-5139. Further evidence of the high correlation between carcinogenicity and mutagenicity. Lists chemicals. Both DDE and dieldrin were negative by the Ames test.

McCann, J.; N. E. Spingarn; J. Kobori; and B. N. Ames. 1975. "Detection of carcinogens as mutagens: Bacterial tester strains with R factor plasmids". *Proceedings of the National Academcy of Sciences*, vol. 72, pp. 979-983. New strains that increase sensitivity of Ames test.

McDermott, W. 1961. "Air pollution and public health". *Scientific American*, October. A perceptive early statement of the likely dangers.

McGinty, Lawrence. 1976. "The graveyard on Milan's doorstep". *New Scientist*, August 19, 1976, pp. 383-385. On the toxicity of dioxin, a chlorinated hydrocarbon that can contaminate 2,4,5-T.

McMichael, W. C. 1973. "Tobacco smoke and energy conservation". *Building systems design*, vol. 70, October/November, pp. 17-18. Smokers at convention increase energy requirements for airconditioning six-fold.

Menard, H. W. 1974. "Geology, resources, and society". W. H. Freeman, San Francisco. Chapter 14 is an excellent treatment of ground subsidence and landslides caused by various human activities.

Merless, R. R. 1971. "Talc-treated rice and Japanese stomach cancer". *Science*, vol. 173, pp. 1140-1141 (September 17). Presents evidence that asbestos-contaminated talc on rice in the diet is the carcinogen or cocarcinogen responsible for the high incidence of stomach cancer in Japan.

Meselson, M. 1970. "Behind the Nixon policy for chemical and biological warfare". *Bulletin of the Atomic Scientists*, January. Indicates nations lacking nuclear capability need these weapons more than the United States does.

-----. 1970. "Chemical and biological warfare". *Scientific American*, May. General survey of the subject.

Metcalf and Eddy, Inc. 1972. "Wastewater engineering". McGraw-Hill, New York. A technical handbook of water treatment methods.

Miller J., and E. C. Miller. 1971. "Chemical carcinogenesis: Mechanisms and approaches to its control". *Journal of the National Cancer Institute*, vol. 47, pp. v-xiv. Contains an important summary of the mechanism of activation (changing noncarcinogens into carcinogens).

Miller, R. W. 1969. "Delayed radiation effects in atomic-bomb survivors". *Science*, vol. 166, pp. 569-574 (October 31). Summary of observations on the survivors of Hiroshima and Nagasaki.

Miller, Stanton S., ed. 1974. "Water pollution". American Chemical Society, Washington, D.C. One hundred six articles from the journal *Environmental Science and Technology*, strong on monitoring and control.

Mirvish, S. S.; L. Walleave; M. Eagen; and P. Shubeck. 1972. "Ascorbate-nitrite reaction: Possible means of blocking the formation of carcinogenic N-nitroso compounds"

nitrite reaction: Possible means of blocking the formation of carcinogenic N-nitroso compounds. *Science*, vol. 177, pp. 65-68 (July 7). Salts of ascorbic acid (Vitamin C) may block formation of nitrosamines in the digestive tract.

Müller, A. R. 1975. "Noise as a health hazard". *Ambio*, vol. 4, no. 1, pp. 6-13. Excellent introduction to physiological basis of hearing impairment from noise, emphasizing individual variation in susceptibility.

-----. 1977. "How good are the work noise standards?" *New Scientist*, January 27, pp. 192-194. Noise influences organs other than ears.

Monath, T. P.; V. F. Newhouse; G. E. Kemp; H. W. Setzer; and A. Cappiapuoti . 1974. "Lassa virus isolation from Mastomys natalensis rodents during an epidemic in Sierra Leone". *Science*, vol. 185, pp. 263-265 (July 19). Extrahuman cycle demonstrated in a rodent inhabiting houses.

Morgan, J. J. 1972. Trace metals in the environment. In *Science, scientists, and society*, W. Beranek, Jr., ed. Bogden and Quigley, New York. Useful compilation of data and discussion.

Morgan, Karl Z. 1975. "Suggested reduction of permissible exposure to plutonium and other transuranium elements". *American Industrial Hygiene Association Journal*, August, pp. 567-575. An eminent health physicist suggests that the linear hypothesis may underestimate effects at low doses.

Murozumi, M.; T. S. Chow; and C. Patterson. 1969. "Chemical concentrations of pollutant lead aerosols, terrestrial dusts and sea salts in Greenland and Antarctic snow strata". *Geochimica et Cosmochimica Acta*, vol. 33, p. 1247.

National Academy of Sciences (NAS). 1971. *Fluorides*. NAS, Washington, D.C. A review of the evidence.

-----. 1972. *Accumulation of nitrate*. NAS, Washington, D.C. Nitrate water pollution and its effects on human health.

-----. 1972. *Airborne lead in perspective*. NAS, Washington, D.C.

-----. 1972. *The effects on populations of exposure to low levels of ionizing radiation* (BEIR Report). NAS, Washington, D.C. Estimates number of cancer deaths and genetic defects in the U.S. population due to low-dose radiation, based on linear hypothesis of effects versus dose.

-----. 1974. *Air quality and automobile emissions control. vol. 3, The relationship of emissions to ambient air quality*. NAS, Washington D.C. A detailed and very useful document, with an extensive bibliography.

-----. 1974. *Geochemistry and the environment*. NAS, Washington, D.C.

-----. 1976. *Contemporary pest-control practices and prospects: The report of the executive committee*. NAS, Washington, D.C. Contains a good summary of the problem of detecting carcinogenic chemicals.

National Clearinghouse for smoking and health. Annual. *Bibliography of smoking and health*. Center for Disease control, U.S. Department of Health, Education and Welfare, Atlanta. Abstracts of international literature on smoking and health, including effects of smoking on nonsmokers.

Natusch, D.; J. Wallace; and C. Evans. 1974. "Toxic trace elements: Preferential concentration in respirable particles". *Science*, vol. 183, pp. 202-204 (January 18). Shows most of the heavy metals concentrate in the smallest particles emitted from fuel combustion.

Neri, L. C.; D. Hewitt; G. B. Schreiber; T. W. Anderson; J. S. Mandel; and A. Zdrojewsky. 1975. "Health aspects of hard and soft waters". *Journal of the American Water Works Association*, August, pp. 403-409. Detailed technical treatment of correlation of disease and water softness.

Nero, A. V., and Y. C. Wong. 1977. *Radiological health and related standards for nuclear power plants*. Lawrence Berkeley Laboratory, University of California. LBL-5285. Excellent job of sorting out various national and international standards and presenting them in readable form.

New Scientist. 1975. "Mental deficiency and lead linked in new survey". March 20, p. 692.

-----. 1976. "U.S. bans commonest red food colour". January 29, p. 215.

Newton, K. G., and N. C. Greene. 1972. "Organochlorine pesticide residue levels in human milk, Victoria, Australia, 1970", *Pesticides Monitoring Journal*, vol. 6, pp. 4-8. DDT-R averaged 0.139 parts per million for rural and 0.145 parts per million for urban mothers. Gives FDA tolerance for cow's milk.

Nobbs, C. L., and D. W. Pierce. 1976. "The economics of stock pollutants: The example of cadmium". *International Journal of Environmental Studies*, vol. 8, pp. 245-255. Difficulties of conventional costbenefit analysis in dealing with persistent pollutants.

Nordberg, G. F. 1974. "Health hazards of environmental cadmium pollution". *Ambio*, vol. 3, no. 2, pp. 55-66. Excellent review article.

Norwood, W. D.; and C. E. Newton, Jr. 1975. "U.S. transuranium registry study of thirty autopsies". *Health Physics*, vol. 28, pp. 669-675. Discusses how plutonium distributes itself in the human body, and notes that the number of deaths that have occurred to date among workers exposed to plutonium and among unexposed but otherwise similar control groups is inadequate to permit conclusions concerning what body burden of plutonium is sufficient to cause cancer.

Nottingham, J. 1972. "The dangers of chemical and biological warfare (CBW)". *Ecologist*, February, pp. 4-6. An overview of the threat.

O'Brien, R. D. 1967. *Insecticides: Action and metabolism*. Academic Press, New York. Information on chemistry and metabolism of DDT and other pesticides.

Oswald, W. J. 1976. Engineering applications. In *Handbook of microbiology*, 2d edition. CRC Press, Cleveland. Novel approaches to waste treatment using bacteria, algae, and solar energy.

Otani, K., and J. Ui. 1972. Minimata disease. In *Polluted Japan*, J. Ui. ed., pp. 14-16.

Page, T.; R. H. Harris; and S. S. Epstein. 1976. "Drinking water and cancer mortality in Louisana". *Science*, vol. 193, pp. 55-57 (July 2). Statistical analysis indicates a relationship between cancer mortality rates and drinking water from the Mississippi River.

Parr, A. E. 1968. "The five ages of urbanity". *Landscape*, vol. 17, no. 3. Describes the impact of modern city life on people of different ages.

Patterson, C. C. 1965. "Contaminated and natural lead environments of man". *Archives of Environmental Health*, vol. 11, pp. 344-360. Still the best survey of the lead problem.

Perkins, E. J., 1976. The evaluation of biological response by toxicity and water quality assessments. In R. Johnston, ed., *Marine pollution*, pp. 505-585. Examines in detail how the effects of insults to marine ecosystem are determined.

Perlmutter, M., and M. Lieber. 1970. *U.S. geological survey, water supply paper 1879 G.* Washington, D.C. Discusses chromium and cadmium pollution of Long Island ground water.

Pichirallo, J. 1971. "PCB's: Leaks of toxic substances raises issue of effects, regulation". *Science*, vol. 173, pp. 899-902 (September 3). Details of egg-contamination episodes.

Polunin, Nicholas, ed. 1972. *The environmental future*. Macmillan, London. Contains many sections relevant to this chapter.

Pott, Sir Percival. 1775. "Chirugical observations relative to the cataract, the polypus of the nose, the cancer of the scrotum, the different kinds of ruptures, and the mortification of the toes and feet". Hawes and Collins, London. (Reprinted in *National Cancer Journal Monograph*, vol. 10, pp. 7-13.) Pott made the first link between an environmental factor (chimney soot) and cancer.

President's Science Advisory committee (PSAC). 1973. *Chemicals and health*. Government Printing Office, Washington, D.C. An important source of summary data on chemicals in the environment.

Pressman, J., and A. Carol. 1971. "Crime as a diseconomy of scale". *Review of Social Economy*, vol. 29, pp. 227-236. No relationship found between crime and crowding.

Quarles, John R. 1977. "National water quality: assessing the mid-course correction". *Sierra Club Bulletin*, February, pp. 14-17. Acting administrator of the EPA reports on progress in controlling water pollution.

Radomski, J. L.; W. B. Deichmann; E. E. Clizer; and A. Rey. 1968. "Pesticide concentrations in the liver, brain, and adipose tissues of terminal patients". *Food and Cosmetic Toxicology*, vol. 6, pp. 209-220. Correlation of home use of pesticides, pesticide concentrations in fat, and various causes of death.

Rail, David P. 1974. "Review of health effects of sulfur oxides". *Environmental Health Perspectives*, August, p. 97ff.

Ramanathan, N. L., and S. Kashyap. 1975. "Occupational environment and health in India". *Ambio*, vol. 4, no. 1, pp. 60-65. An overview.

Redmond, C. K.; A. Ciocoo; J. W. Lloyd; and H. W. Rush. 1972. "Long-term mortality study of steelworkers: pt 6, Mortality from malignant neoplasms among coke oven workers". *Journal of Occupational Medicine*, vol. 14, pp. 621-629. Workers in the vicinity of coke ovens suffer greatly increased cancer load in comparison with those in other parts of steel plant. Useful bibliography.

Reeves, A. L.; H. E. Puro; and R. G. Smith. 1974. "Inhalation carcinogenesis from various forms of asbestos". *Environmental Research*, vol. 8, pp. 178-202. Animal tests and review of hypotheses about two main types of cancer caused by asbestos.

Rubin, H. 1976. "Carcinogenicity tests". *Science*, vol. 191, p. 241. Criticizes view that cancers originate as mutations in body cells (see Ames, Carcenogenicity tests).

Sachs, D. P. 1970. "Work at your own risk". *Saturday Review*, June 6, pp. 64-65. Reports death of a child who sucked finger after putting it into a can of TEPP.

Sander, J., and F. Seif. 1969. "*Bakterielle Reduktion von Nitrat im Magen des Menschen als Ursache einer Nitrosamin-Bildung*". *Arzneimittellehre Forschung, vol. 19, p. 1091. Sodium nitrate and a secondary amine (diphenylamine) were given to thirty-one human subjects and nitrosdiphenylamine was later detected in the stomach contents.*

Sanders, H. J. 1969. "Chemical mutagens: pt. 1, The road to genetic disaster; pt. 2, An expanding roster of suspects". Chemical and Engineering News, May/June. An excellent popular summary, somewhat dated but still valuable.

Savage, E. P.; J. D. Tessari; J. N. Malberg; H. W. Wheeler; and J. R. Bagby . 1973. "Organochlorine pesticide residues and polychlorinated biphenyls in human milk, Colorado, 1971-1972". Pesticide Monitoring Journal, vol. 7, p. 15. Total organochlorines and PCBs ranged from 27 to 521 parts per billion.

Schild, G. 1970. Hong Kong "flu": Problems of prediction. New Scientist, October 29, p. 222. The causes of epidemics, both the immunological and other biological properties of the virus and extrinsic factors like the weather, are still poorly understood.

Schmeltz, I., D. Hoffmann; and E. L. Wynder. 1975. "The influence of tobacco smoke in indoor atmospheres: pt. 1, An overview". Preventive Medicine, vol. 4, no. 1, pp. 66-82. Good literature review of studies of contaminant concentrations and possible effects on nonsmokers.

Schmidt, F. 1974. "Tabakrauch als wichtigste Luftverschmutzung in Innenraumen und als pathogenische Noxe für Passivräucher". Medizinische Welt, vol. 25, no. 44. Good review article on the effects of passive smoking, including cancer risk, allergic reactions, and sensitivity of children.

Schroeder, H. A. 1971. "Trace elements in the human environment". Ecologist, May, pp. 15-19. Good review article.

Schuck, P. H., and H. Wellford. 1973. "Botulism and nitrites". Science, vol. 180, p. 1322 (June 29). Disagrees with Wolff and Wasserman, Nitrates, nitrites and nitrosamines (see their reply adjacent, and Lijinsky, Nitrites in foods).

Schwartz, H. 1972. "Influenza: yes, you really had it". New York Times, February 13. Graph of epidemics from September 1969 to February 1972.

Selikoff, I. J. 1975. "Recent perspectives in occupational cancer". Ambio, vol. 4, no. 1, pp. 14-17. Survey of recent experience emphasizing the difficulties in evaluation and prevention that arise from long latency period between insult and incidence of disease.

Selikoff, I. J.; R. A. Bader; M. E. Bader; J. Churg; and E. C. Hammond. 1967. "Asbestos and neoplasia". American Journal of Medicine, vol. 42, pp. 487-496. Good summary of the massive threat of asbestosinduced cancer; bibliography of early literature.

Selikoff, I. J.; E. C. Hammond; and J. Churg. 1968. "Asbestos exposure, smoking, and neoplasia". Journal of the American Medical Association, vol. 204, pp. 106-112. Synergism involving asbestos fibers and tobacco smoke.

Shea, Kevin P. 1973. "PCB: The worldwide pollutant that nobody noticed". Environment, vol. 15, November, pp. 25-28. A general review.

-----. 1977. "Profile of a deadly pesticide". Environment, vol. 19, January/February, pp. 6-12. Deals with the neurotoxic organophosphate Phosvel (leptophos) which may be able to cause crippling disease.

Shettigara, P., and R. W. Morgan. 1975. "Asbestos, smoking, and laryngeal carcinoma". Archives of Environmental Health, vol. 30, pp. 517-519. Bibliography gives access to literature on cancers caused by asbestos.

Shy, C. M.; J. P. Creason; N. E. Pearlman; C. E. McClain; F. B. Benson; and M. M. Young. 1970. "The Chattanooga school children study: Effects of community exposure to nitrogen dioxide, pts. 1 and 2". Journal of the Air Pollution Control Association, vol. 20, p. 539-545 (August) and pp. 582-588 (Sept.).

Smith, C. E. G.; D. I. H. Simpson; E. T.W. Bowen; and I. Zlotnik. 1967. "Fatal human disease from vervet monkeys". Lancet, vol. 2, no. 7526, pp. 1119-1121. (See also pp. 1129-1130 of the same issue.) Source on Marburgvirus.

Smith, W. H. 1972. "Lead and mercury burden of urban woody plants". Science, vol. 176, p. 1237-1239 (June 16).

Sobsey, M. D. 1975. "Enteric viruses and drinking-water supplies". Journal of the American Water Works Association, August, pp. 414-417. Problems of detection and surveillance.

Sommer, R. 1969. "Personal space". Prentice-Hall, Englewood Cliffs, N.J. Special emphasis on design of buildings to fit peculiarities of human space requirements.

Sparks, R. E.; J. Cairns, Jr.; and A. G. Heath. 1972. "The use of bluegill breathing rates to detect zinc". *Water Research*, vol. 6, pp. 895-911. A bioassay for a nonlethal toxicant.

Stocker, Paul G., ed. 1968. "The Merck Index: An encyclopedia of chemicals and drugs". 8th ed. A standard reference work describing an enormous array of chemicals (some 42,000 in this edition) and giving structural formulas for about 10 percent of them. Information on synthesis, characteristics, uses, and toxicity.

Stein, P. C.; E. E. Campbell; W. D. Moss; and P. Trujillo. 1974. "Mercury in man". *Archives of Environmental Health*, vol. 29 (July), pp. 25-27. Good reference on the fate of mercury once in the body.

Stoltz, D. R.; K. S. Khera; R. Bendall; and S. W. Gunner. 1970. "Cytogenctic studies with cyclamate and related compounds". *Science*, vol. 167, pp. 1501-1502 (March 13). Tests with human leucocyte cultures shows these compounds cause chromosome damage.

Tamplin, A. R., and T. B. Cochran. 1974. "Radiation standards for hot particles". Natural Resources Defense Council, Washington, D.C. Argues that under some circumstances plutonium can be 100,000 times more hazardous than existing standards imply -- a factor too large for most other authorities to swallow.

Tanner, J. T.; M. H. Friedman; D. N. Lincoln; L. A. Ford; and M. Jaffee. 1972. "Mercury content of common foods determined by neutron activation analysis". *Science*, vol. 177, pp. 1102-1103 (September 22).

Tardiff, R., and M. Deinzer. 1973. *Toxicity of organic compounds in drinking water*. EPA Water Supply Research Laboratory, Cincinnati. Chlorination of water supplies may itself be a source of carcinogens.

Thompson, R. C. 1975. Transuranium element toxicity -- dose response relationships at low exposure levels. Summary and speculative interpretation relative to exposure limits. In *Radiation Research*, O. Nygaard, H. Adler, and W. Sinclair, eds., Academic Press, New York, pp. 1278-1284. Support for the view that plutonium is perhaps 5 times more hazardous than existing MPCs suggest.

Tinker, J. 1973. "PCBs at Maendy: Scare or disaster?" *New Scientist*, June 21, pp. 760-762. Alarming PCB pollution at one location in Wales.

-----, 1973. "Should public smoking be banned?" *New Scientist*, August 9, pp. 313-315. Excellent concise review of the evidence concerning harmfulness of tobacco smoke to nonsmokers.

Topping, G. 1976. Sewage and the sea. In R. Johnston, ed., *Marine pollution*, pp. 303-351. Calls for action now before the situation gets out of hand.

Trijonis, J. 1975. The relationship of sulfur-oxide emissions to sulfur dioxide and sulfate air quality. In *Air quality and stationary-source emission control*, NAS. The best work on a difficult technical problem.

Trump, C. G. 1974. "Public eye on pollution". *Environment*, vol. 16, no. 10, pp. 13-16. Critique of government practices in regulating water pollution.

Tseng, W. P.; H. M. Chu; S. W. How; J. M. Fong; C. S. Lin; and Shu Yeh. 1968. "Prevalence of skin cancer in an endemic area of chronic arsenicism in Taiwan". *Journal of the National Cancer Institute*, vol. 40, pp. 453-463. Relates high arsenic content of water to skin cancer.

Turner, J. S. 1970. "The chemical feast". *Grossman*, New York. Report of Ralph Nader's study group on the U.S. Food and Drug Administration; see especially material on cyclamates.

Ui, J., ed. 1972. *Polluted Japan*. Jishu Koza Citizens Movement, Tokyo. A shocking, often angry set of articles documenting in words, statistics, and photographs the intense industrial pollution in Japan.

United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR). 1972. *Ionizing radiation: Levels and effects*. 2 vol. United Nations, New York. Very detailed review of the evidence. UNSCEAR refuses to extrapolate evidence obtained at high doses to estimate low-dose effects, however.

U.S. Department of Commerce. Annual. *Statistical abstract of the United States*. U.S. Government Printing Office, Washington, D.C.

U.S. Department of Health, Education and Welfare. 1964. *Smoking and health*. Government Printing Office, Washington, D.C. The summary of why those who claimed cigarettes to be the equivalent of coffin nails were correct.

-----. 1969. *Air quality criteria for sulphur oxides*. Government Printing Office, Washington, D.C. Somewhat dated but still useful compendium of information on effects and bases for early standards.

-----. 1970. *Radiological health handbook*. Government Printing Office, Washington, D.C. Useful tabulations of energies of radioactive emissions and shielding factors for various materials.

U.S. Environmental Protection Agency (EPA). 1971. *Effects of noise on people*. NTID 300.7. National Technical Information Service, Springfield, Va. Valuable basic reference.

-----. 1971. *Environmental lead and public health*. Report AP-90. Air Pollution Control Office, Research Triangle Park, North Carolina.

-----. 1971. *Fundamentals of noise: Measurement, rating schemes and standards*. National Technical Information Service, Springfield, Va., NTID 300.15.

-----. 1972. *The economics of clean water, summary*. Government Printing Office, Washington, D.C. Extent of various degrees of sewage treatment in the U.S., among other topics.

-----. 1973. *Compilation of air pollutant emission factors*. 2d ed. EPA, Washington, D.C.

-----. 1975. *DDT: A review of scientific and economic aspects of the decision to ban its use as a pesticide*. EPA, Washington, D.C., EPA-540/1-75-022. Self-justifying but full of useful information.

-----. 1975. *A study of indoor air quality*. EPA-USO/4-74-02. EPA, Washington, D.C. Presents measurements of concentrations of oxides of nitrogen and carbon monoxide in homes due mainly to operation of gas stoves.

U.S. Federal Water Pollution Control Administration. 1968. *Cost of clean water*, vol. 3. Government Printing Office, Washington, D.C. Character and origins of the plight of Lake Erie.

U.S. General Services Administration. 1976. Code of federal regulations, title 10, *Energy*, parts 20 and 50. Standards for protection against radiation.

U.S. National Commission on Materials Policy. 1974. *Material needs and the environment today and tomorrow*. Government Printing Office, Washington, D.C. Contains useful material on civilization's flows of heavy metals.

U.S. National Council on Radiation Protection and Measurements. 1975. *Natural background radiation in the United States*, NCRP Publications, Washington, D.C., report 45. Very thorough discussion of contributions of cosmic rays and naturally occuring isotopes to doses in the U.S., with an appendix on fallout from weapons tests.

U.S. Nuclear Regulatory Commission. 1975. *Reactor safety study*. Government Printing Office, Washington, D.C., WASH 1400/NUREG-75-14. Many details of shielding, pathway, and dosimetry calculations.

Vallentyne, J. R. 1972. "Freshwater supplies and pollution: Effects of the demophoric explosion on water and man". *The environmental future*, N. Polunin, ed., Macmillan, London, pp. 181-199. An excellent overview. Coins the word *demophoric* to "encompass all aspects of the biology of human populations and technological productionconsumption." Thus, we are undergoing a demophoric explosion.

van der Frits Leeden. 1975. "Water resources of the world: Selected statistics". Water Information Center, Port Washington, N.Y. Extensive information on water-quality standards and extent of water pollution around the world.

Wade, N. 1972. "DES: A case study of regulatory abdication". *Science*, vol. 177, pp. 335-337 (July 29). Another USDA-FDA foul-up discussed.

-----. 1972. "Delaney anti-cancer clause: Scientists debate on article of faith". *Science*, vol. 177, pp. 588-591 (August 18).

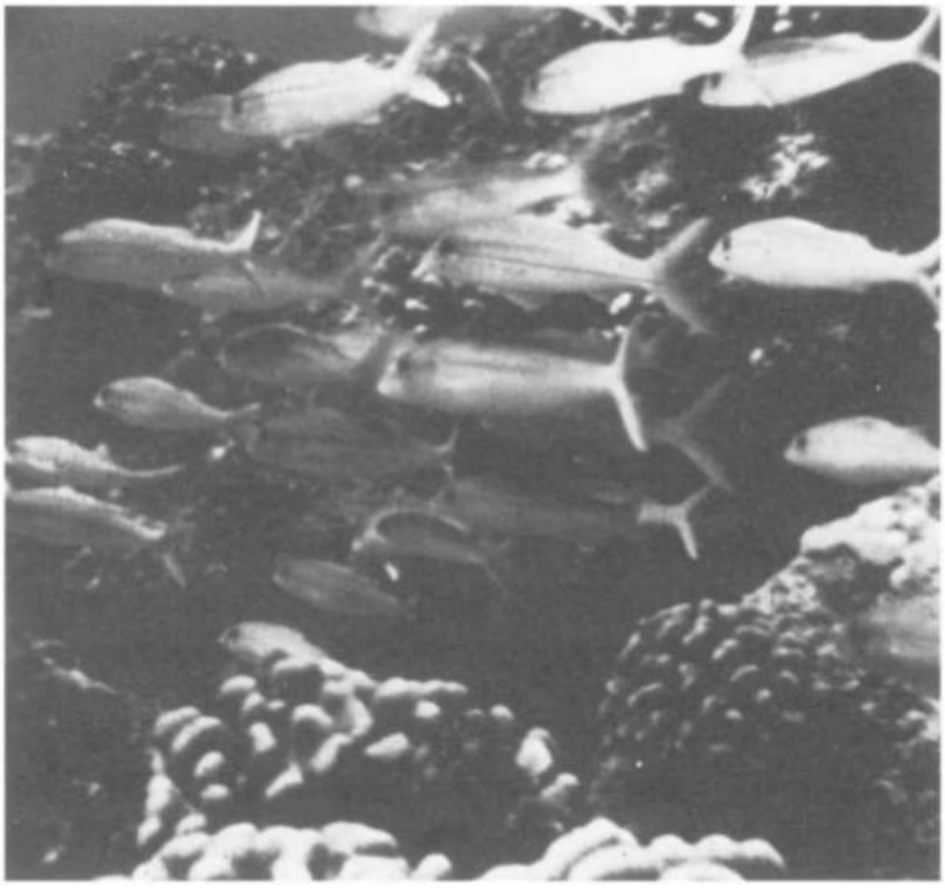
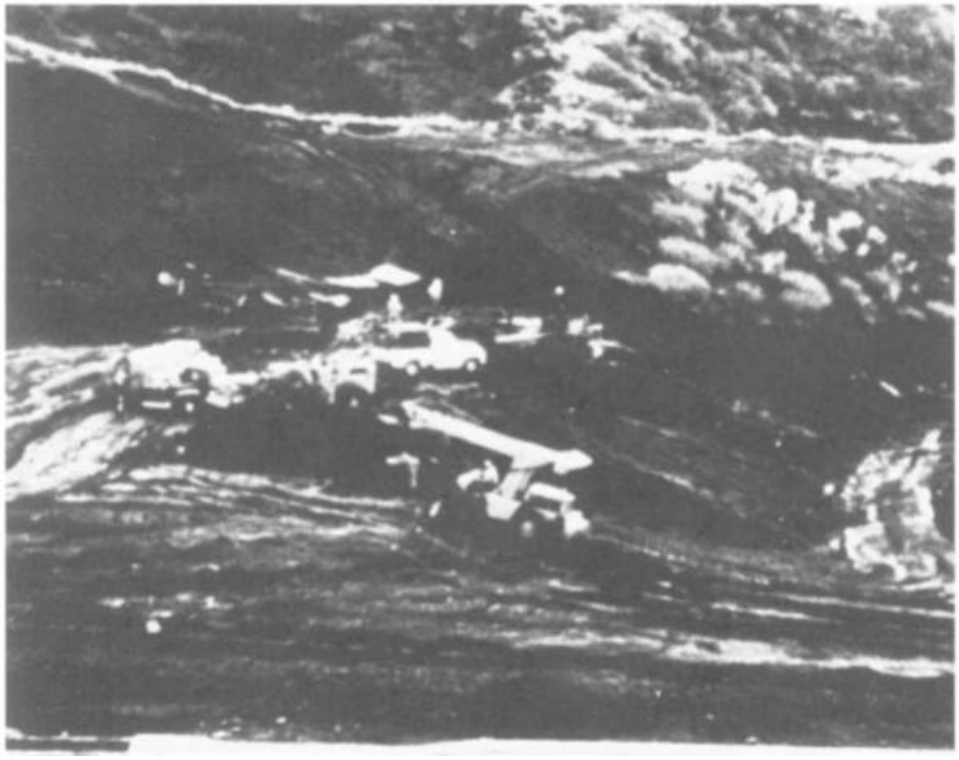
CHAPTER 11
Disruption of Ecological Systems

I suggest that the earth's biota is our single, most important resource. While protecting it will not assure wealth and grace for man, its decimation will assure increasing hardship for all



- G. M. Woodwell *Success, Succession, and Adam Smith*, 1974



The direct effects of pollution on property, on human health, and on the quality of life are varied and important, but they may ultimately prove to be less critical for society as a whole than the less obvious effects of pollution and other human activities on the ecological systems that sustain human life.

Crucial to these systems are the green plants that are the basic energy source for all other forms of life on Earth, and green plants are provided with the material ingredients of growth by the nutrient cycles of the biosphere. Those cycles do routinely what human society as yet cannot do -- convert wastes completely into resources, using energy from the sun. The crops of civilization are watered, nourished, and protected from potential pests with considerable help from natural processes, which include the formation and preservation of soil itself. The agents and carriers of human disease, like crop pests, are controlled more often by natural enemies or by environmental conditions than by human action. Climate and the composition of the atmosphere itself are regulated by geophysical and biological processes that may be susceptible to human interference.

These and other "public services" of the global ecosystem cannot be replaced by technology now or in the foreseeable future. This is so in many instances because a process is not understood scientifically. And, even where scientific knowledge might be adequate, the sheer magnitude of the tasks performed by natural

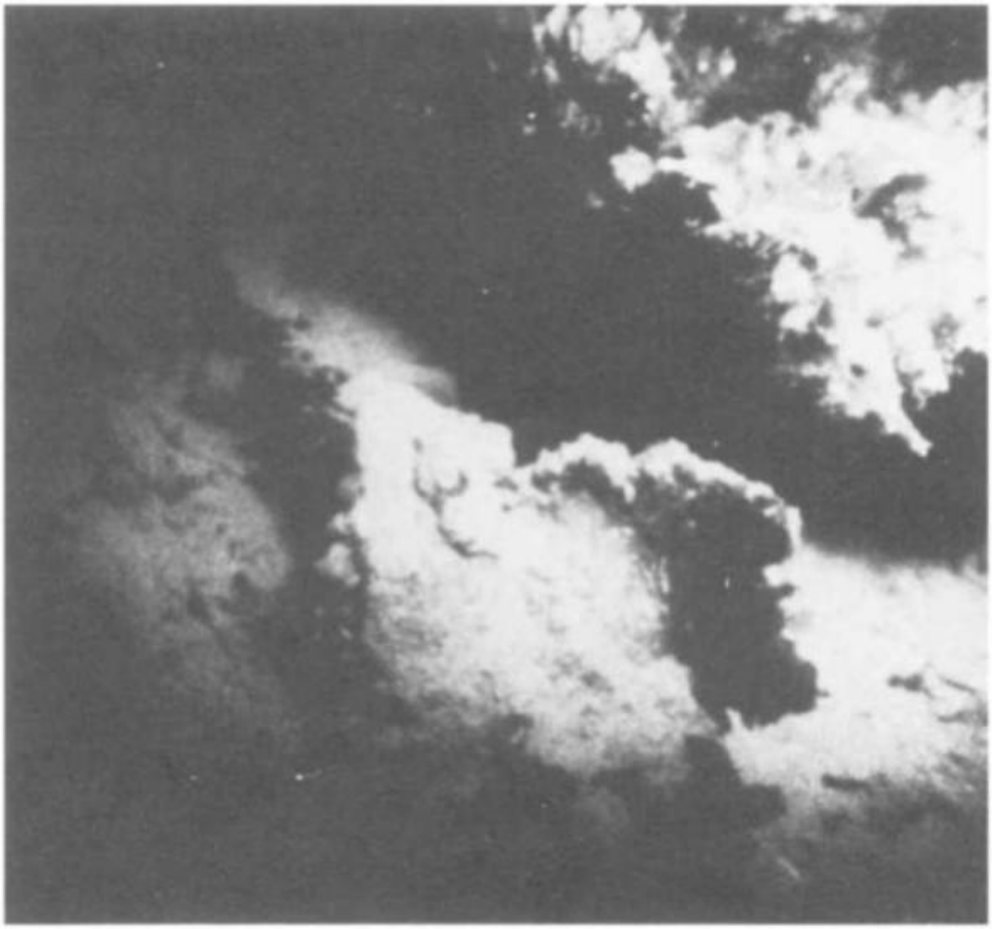


FIGURE 11-1 Destruction of coral reefs at Kaneohe Bay, Oahu, Hawaii, as a result of the building of subdivisions. A and B, "before." A. Complex reef community before intrusion of silt and sewage; prominent are butterfly fishes (*Chaetodon lunula*), which are characteristic of coral communities, feeding on the reef fauna of invertebrates. B. A school of goatfishes (*Mulloidichthys samoensis*), which are prized as food. They feed on small animals in sandy bottoms among the coral growths. C. Construction of subdivisions on slopes above the bay with inadequate erosion control. Heavy downpours wash large amounts of silt into Kaneohe Bay. D and E, "after." D. Silt settling on and killing coral growths by overloading the self-cleaning abilities of the tiny animals that secrete the hard coral skeletons. E. "Graveyard" of coral killed by silt and sewage from subdivisions. Note the greatly reduced diversity of life and the presence of a species of sea cucumber, regarded by some marine biologists as indicators of heavy pollution. The complex, stable reef system, which once provided edible fishes and aesthetic values for people, has been replaced by a destabilized simple system featuring the population explosion of a "garbage" organism. (From the film Cloud Over the Coral Reef by Dr. Lee Tepley and Dr. R. E. Johannes .)

ecosystems dwarfs civilization's capacity to finance, produce, and deploy the technology necessary to replace them.

Since the support provided for human life by ecosystems is indispensable and irreplaceable, it is essential that the mechanisms behind those vital functions -- and the potential for disrupting them through pollution and other human activities -- be carefully studied. [1] The mechanisms were discussed in chapters 2, 3, and 4. This chapter is an introduction to the disruptions.

MODIFYING ECOSYSTEMS

Like any other creatures, human beings have always had some effect on the ecological systems of which they were a part, but the history of deliberate and significant modification of ecosystems doubtless began with the development of agriculture. [1a] Since then, human influence has reached to the remotest areas of the planet and has been intensified by increasing numbers of people and the development of modern technology.

What are some of the ways in which humanity modifies ecological systems? Obviously, some ecosystems are destroyed outright by such diverse activities as clearing land to plant crops, starting fires, building dams, applying defoliants to jungles, constructing buildings, and laying pavement. (See Figure 11-1 for an example of how activities on land can damage an ecosystem in an adjacent bay.) Forests are chopped down for structural wood and firewood. [2] Estuaries are dredged, filled, or altered by bulkheads. [3] And, as discussed later in Box 11-3, ecosystems can be destroyed as a part of military strategy.

The effects of such assaults are diverse. Paved areas are normally removed from natural systems for long periods -- and their rapid reclamation is both costly and difficult. Dams take land out of terrestrial systems for long periods, but as noted earlier, dams are temporary structures, and enriched land will eventually be returned. Strip-mined areas in developed countries (some 1.6 million hectares in the United States and 2.2 million hectares in the USSR by 1974) [4] often have not been reclaimed; the practicability of doing so at all is a function of both economics and ecology. [5] When prairie is converted to cornfield, an unstable ecosystem replaces a stable one. Attempts to stabilize such systems artifically can lead to further destabilization and bring about changes elsewhere as well.

Physical assaults on ecosystems often interact with overexploitation and pollution to threaten species with extinction. For example, industrial and harbor development encroaching on breeding areas is combining with oil pollution and competition from the fishing industry to deplete South African jackass penguin populations already reduced in size by overexploitation of the bird's eggs and disruption (since halted) of their breeding activities. [6]

Now that ecologists are gaining a more detailed understanding of the factors that threaten ecosystems, they are beginning to examine carefully strategies for preserving natural diversity. Especially interesting have been attempts to develop a guideline for location, number, size, and configuration of natural reserves, based on the theory of island biogeography. [7] Few topics are more worthy of investigation, although, of course, application of the principles uncovered will require a commitment to conservation and a halt to human expansion while there are significant wild areas left to conserve.

Deforestation

The values to human society of healthy forest ecosystems extend far beyond the obvious ones of timber, wood products, and recreational resources. Forest ecologist F. H. Bormann has summarized these additional lessappreciated, but perhaps ultimately more important

---

[1]The subtleties of the interactions that can be discovered by such studies, even when a pastoral society is involved, are illustrated by Stephen Berwick, "The Gir forest: An endangered ecosystem".

values: "Forest ecosystems . . . exercise considerable control over patterns of climate, hydrology, circulation of nutrients, erosion, and the cleansing functions of air and water, as well as over the status of streams, lakes, and underground water supplies." [7a] Moreover, tropical forests especially represent a vast reservoir of genetic diversity of plants, animals, and microorganisms, any of which potentially could be of direct benefit to humanity, and all of which play their parts in maintaining the ecosystem. [7b]

Wholesale logging of forests creates extreme changes that effectively destroy the forest ecosystem. Numerous animals that depend on the trees for food and shelter disappear. Many of the smaller forest plants depend on the trees for shade; they and the animals they support also disappear.

Removal of temperate-zone forests also results in heavy losses of nutrients from the soil. These losses may overload streams with nutrients and, if prolonged, may limit the ability of succession to restore the forest ecosystem. If disruption of a forest floor is severe, widespread erosion losses may become serious. If such disruption is avoided, the potential for recovery remains high if the successional process can begin within a year or two of cutting, since early successional species are adapted to take advantage of the increased abundance of water and nutrients in such areas. [8] In time, if reforestation is not carried out, a deforested area is invaded by pioneer weedy plants that often have far fewer desirable characteristics for human use than did the forest that was removed. As discussed in Chapter 4, areas from which tropical forests have been removed may have much less potential for successional recovery, particularly where soils are lateritic.

Loss of plant cover and topsoil reduces the capacity of an area to retain water, diminishes the supply of fresh water, causes silting behind dams, and has other serious consequences for human beings. The flooding along many of the world's rivers, from the Ganges in India to the Eel River in California, has been greatly aggravated by heavy deforestation in their watersheds.

Deforestation also significantly reduces the amount of water transferred from ground to air by transpiration by trees, which in turn affects climate, at least locally. Downwind of a deforested area, weather is made more arid and subject to greater extremes of temperature. Removal of tropical rainforests also reduces the absorption of incident sunlight. As tropical forests are progressively cleared during the rest of this century, the result may be unanticipated changes in climate, perhaps on a global scale. Indeed, some changes attributable to tropical deforestation have been noted already. [8a]

Human activities have already substantially reduced the world's forests and produced a great increase in the amount of desert and wasteland, as noted in Chapters 4 and 6. Such destructive activities have accelerated as the human population has increased, and in many cases complex interactions between human beings and the environment have led, or have threatened to lead, to *ecocatastrophes* (dramatic failure of the life-support capability of an ecosystem).

Slash-and-Burn Agriculture

One of the clearest examples of how overpopulation can lead to environmental deterioration can be seen in one kind of nonmechanized farming. In tropical forests, people for centuries have practiced what is known variously as slash-and-burn or milpa or swidden agriculture. [9] In that method a clearing is cut in a forest during the driest part of the year and the felled trees left in place. After they have dried, they are burned. The fire not only provides fertile ash, it also kills insects and the seeds of weeds. The farmer plants a crop as rain commences and then injects additional energy into the system in the form of labor -- fighting weeds with hoe and machete.

After the harvest the inedible parts of the crop plants are chopped down, allowed to dry in the field, and burned. Since the mass of plant material is smaller than that of the previous year when the forest was first cleared,

[9]D. H. Janzen, "The unexploited tropics".

the fire is not so hot and there is less ash. As a result the soil is less thoroughly fertilized and the pest kill is less complete. The downhill spiral continues for a year or two until it is no longer profitable to farm that clearing. The milpa farmer then moves on, creates a new clearing, and repeats the whole process. Meanwhile the forest gradually reclaims the original clearing. Tens or hundreds of years later, the original clearing may once again be farmed. [9a]

Because the tropical forest is a tightly closed system as far as nutrient cycles are concerned (Chapter 3), the small, widely spaced clearings of swidden farmers do little damage to that system. Adjacent trees help protect a clearing from the torrential tropical rains, and their roots, extending into the clearing, recapture nutrients. When a clearing is abandoned, the forest can reinvade it. But what happens when human population growth forces farmers to return to previously farmed plots before the forest has totally reclaimed them? Or when clearings are made larger in order to support more people?

When a sizable chunk of forest is cleared for agriculture (or defoliated for military purposes), the continuous recycling of nutrients is interrupted. The surrounding forest no longer breaks the force of the rain, and tree roots penetrate only the periphery of the clearing. Heavy rains wash away the thin supply of soil nutrients, of which the last to go (where they are present) are iron and aluminum oxides. When certain iron-rich lateritic soils, which underly perhaps 5 to 10 percent of tropical forests, are eroded and exposed to sun and oxygen, a series of complex chemical changes may take place, resulting in the formation of a rocklike substance called laterite (from *later*, the Latin word for brick). Laterization has occurred over wide areas of the tropics, starting long ago and continuing in recent years. Those who have been fortunate enough to visit Angkor Wat in Cambodia (Figure 11-2) have seen magnificent cities and temples built by the Khmers 800 to 1000 years ago. The construction materials were sandstone and laterite, and laterization may have been a principal reason for the disappearance of the Khmer civilization shortly after its greatest monuments were constructed. After lateriza-

FIGURE 11-2 Laterite construction in the temple of Angkor Wat near Ankor Thom, a major city of the ancient Khmer civilization in what is now Cambodia. Laterite on exposure to air turns into a bricklike form of rock still widely used for construction. (Photo by United Nations.)

tion, unfortunately, the forest normally is unable to reinvade a clearing successfully. Even without laterization, a cleared area will rapidly lose the nutrients required for satisfactory

agricultural yields -- nutrients that can only be restored by forest regrowth or by careful fertilization.

Catastrophic loss of soil fertility is thus a natural consequence of increased population density among slash-and-burn agriculturalists. In order to support more people, the age-old patterns of movement are accelerated. [10] Sites of previous clearings are revisited before the

[10]The cultural consequences are discussed in A. P. Vayda, ed., *Environment and cultural behavior*. See especially the paper by Vayda, "Expansion and warfare among swidden agriculturalists".

[9a]For an interesting description of swidden agriculture in New Guinea, where farmers show clear understanding of local ecology and work with it rather than against it, see Roy A. Rappaport, "Forests and man".

forest has totally reclaimed them. As a result, the fires are less hot, the ash less abundant, and soil fertility decreased. Clearings must be abandoned ever more often, and, to compensate, larger clearings are made. The road to soil deterioration is open.

The general pattern described has been repeated in many tropical areas when and where the human population has increased. It has been hypothesized that overintensive tropical agriculture contributed to the collapse of both the Khmer and the classic Mayan civilizations -- although it seems likely that both of those societies had advanced to permanent, rather than milpa cultivation before laterization and other problems overtook them. [11]

Farming the Tropics

A traveler in the tropics today cannot help being impressed by the poor quality of much of the land cleared of forest there. At best, a great deal of that land can serve only as second-rate pasture. Silting of rivers is also easily observed, but subtle changes in climate resulting from removal of forest are less obvious.

Tropical forests are usually able to reinvade small clearings where soils are subject to laterization before the process is complete. Whether large areas that have been kept cleared for substantial periods of time can be reforested after laterization is an open question. Reforestation has been successful in some areas where the soil crust has been carefully broken up, fertilizers applied, and the entire system carefully cultivated. But natural reforestation (and, especially, reestablishment of a semblance of the original diversity) seems unlikely. Even most of the attempts supported by human activity have failed. Laterization is continuing in various parts of the tropics and will doubtless proceed more rapidly as people become increasingly desperate for food. According to one geologist, Mary McNeil, "The ambitious plans to increase food production in the tropics to meet the pressure of the rapid rise of population have given too little consideration to the laterization problem and the measures that will have to be undertaken to overcome it." [12] She points to one fiasco at Iata in the Amazon basin, where the government of

Brazil once attempted to found a farming community. Laterization destroyed the project, when "in less than five years the cleared fields became virtually pavements of rock."

The degree of threat to tropical agriculture posed by lateritic soils is a matter of controversy. [13] Unfortunately, tropical soils are not well understood, so prediction of the consequences of clearing tropical forests for agricultural purposes is difficult.

Some things can be said with assurance, however. First of all, the term *the tropics* covers a multitude of sins. Far from being uniform, the tropics are more diverse ecologically than the temperate regions. Therefore, the ecological and agricultural situation for each location must be evaluated separately. And, furthermore, that evaluation may not provide quick and easy solutions to the problems of agricultural development. For instance, much of the Amazon Basin presents a severe challenge to agriculture. With great effort and care, successful agricultural programs could be developed to farm the so-called *terra firme* -- land above the floodplains that are periodically inundated (and thus fertilized) by the Amazon. Such programs would involve the interlocking of farming with animal husbandry, to make manure available for fertilizer (it tends to be much more satisfactory under tropical conditions than inorganic fertilizers). The constraints on agriculture in Amazonia, moreover, are such as to make difficult the continual adjustments necessary to meet changing local and international market conditions. [14]

The Trans-Amazonian Highway

In 1970, Brazil began a crash program of highway constuction in the Amazon basin. The central project is the Trans-Amazonian Highway. When completed, the highway is to connect such Atlantic coast ports as Belem and Recife with points in Peru and Bolivia, through

---

[11] Although it has been widely stated that the classic Maya were primarily milpa agriculturalists, some recent work indicates otherwise. See B. L. Turner, II, "Prehistoric intensive agriculture in the Mayan lowlands".

[12] Lateritic soils. See also McNeil's "Lateritic soils in distinct tropical environments: Southern Sudan and Brazil".

[13] See, for example, P. W. Richards, *The tropical rainforest*, University Press, Cambridge, 1964; C. N. Williams and K. T. Joseph, *Climate, soil and crop production in the humid tropics*; Betty J. Meggers, "Amazonia: Man and culture in a counterfeit paradise"; and, especially, P. H. Sanchez and S. W. Buol, "Soils of the tropics and the world food crisis".

[14] Harold Sioli, "Recent human activities in the Brazilian Amazon region and their ecological effects". See also B. J. Meggers' article in the same volume.

which countries they may someday be linked by road to the Pacific. The route of the Trans-Amazonian Highway runs roughly parallel to the river itself, about 320 kilometers to the south. The highway is planned to tie in with an extensive additional network of roads crisscrossing the basin. [15]

The program was initiated by President Emilio Médici after he had visited the drought-devastated northeast of Brazil in 1969, in order "to carry the landless population of the Northeast to the unpopulated lands of the Amazon." An agritown of forty-eight to sixty families is planned for every 10 kilometers along the 4800kilometer length of the highway. The government has expropriated all land within 50 miles of the road network (an area of almost 2.3 million square kilometers -- much larger than Mexico), on which it plans to establish colonists on 100-hectare (250-acre) parcels. [16]

Some 8000 Amazonian Indians are to be resettled from the development area onto reservations in a move reminiscent of United States policy in the nineteenth century. Although eighty-four Brazilian social scientists signed a protest against the plan for the Indians, it is clear that the development project will be permitted to move ahead. [17] The great Amazonian rain forest, complete with its rich array of animals and peoples, appears destined to follow the tall-grass prairies of North America to extinction. But the tragedy of the Amazon will be even greater. The European successors of the North American Indians at least were able to extract great wealth on a continuing basis from the lands they appropriated. But the current efforts of the Brazilians will, in all probability, merely net them a few harvests at the cost of irreversible destruction of the region. Amazonia could be turned into the world's largest parking lot.

The tragedy is all the greater because there have been ample warnings for Brazilians -- warnings from home, not just from foreign ecologists. The failure of the agricultural colony set up at Iata was one portent. But the Brazilian government, like other governments, seems to find it hard to learn from experience. And, like other governments, it also may turn a deaf ear to expertise when politics and special interests are involved. Scientific reports published by a government agency, Instituto Brasileiro de Geografia, pointed out the pitfalls of the development program, warning that "a disaster of enormous proportions" would occur [18] if the policy were carried through.

The key to the situation could be the rumor that groups behind the development were actually interested in opening the Amazon basin for oil and other mineral exploration -- that agriculture was a secondary concern, more of an excuse than anything else. But it is not certain that the forest covers a mineral bonanza.

It is possible that Brazilians do not really want to know the truth about Amazonia, for that would force them to confront the true dimensions of their country. Gone would be myths of untold abundance, of limitless resources, of future world power. Brazilians would have to recognize the biological and physical limits within which their nation must operate in order to survive -much as citizens of the United States in the 1970s have had to face the limitations to their power. But the Brazilians have a tougher job, since they must confront reality *before* they have had their fling at being overdeveloped. And there is little sign that they are ready for that corifrontation. [19]

In Brazil today, one sees a striking example of a ubiquitous phenomenon -- the inability of social systems to respond effectively to imperatives arising from the laws of nature. Since the laws of nature are unlikely to be repealed, it would behoove humanity to see whether the "laws" of social behavior are equally fixed (Chapters 14 and 15). If they prove to be, as some social scientists seem to think, then the outlook for *Homo sapiens* is bleak indeed.

Desertification and the Sahel Famine

Another dramatic example of the interaction of human population size with natural systems is seen in the Sahel famine. (The Sahel is the region of Africa on the southern fringe of the Sahara.) The climatic events

[15] *Time*, September 13, 1971.

[19] See, for instance, Para SEMA, "*Ehrlich revela meisa-verdades*", *O Estado de Sao Paulo, January 15, 1975. For a general review of the Brazilian situation, see J. C. Jahoda and D. L. O'Hearn, The reluctant Amazon basin.*

triggering the famine are discussed later in this chapter, but people themselves played a major role in creating conditions in which famine could be triggered. In some areas, for instance, colonial officials misinterpreted the ecologically sound pastoral systems of nomads living in the arid region as inefficient and wasteful. They limited the nomads' movements (the better to govern and tax them) and attempted to commercialize the economy so that meat could be sold. Following the drilling of thousands of wells, the building of storage tanks for water, and the introduction of veterinary medicine, the herds of cattle in the area were greatly increased.

The inevitable result was overgrazing, soil erosion, and desertification -- since the removal of vegetation greatly increases the rate of runoff and thus reduces the beneficial results of rain. [20] As ecologist J. L. CloudsleyThompson wrote, "Man cannot escape responsibility for having created a large part of the Sahara desert. In regions where the needs of the vegetation are delicately balanced by precarious rainfall, overgrazing and the utilization of firewood can have a disastrous and irreversible effect." [21]

The populations of human beings and domestic animals in the Sahel were outstripping the area's ability to produce food and forage before the drought of the late 1960s and 1970s. The repeated failures of the monsoon in the early 1970s were the final blow. The herds of many pastoralists were virtually wiped out. Hundreds of thousands -- perhaps as many as 1.5 million people had died of hunger by the end of 1974. Because the population is scattered and government figures untrustworthy, the true dimensions of the disaster will probably never be known. In Ethiopia, for instance, deliberate attempts were made to cover up the famines. [22]

The way of life of many of the pastoral peoples seems to have been destroyed. Nomadic peoples like the Tuareg, the fabled "blue men" of the desert, have crowded into hideous slums on the margins of povertystricken towns in the southern Sahel. There, on relief, they are turning to farming to supplement their meager rations.

Suggested cures for the problem indicate that no lessons have been learned. The president of Niger has urged, for instance, that international aid be supplied to drill 2500 wells, averaging 300 meters deep, across that country. The cost would be almost a quarter of a billion dollars, and successful completion of the project would almost certainly result in an acceleration of desertification through overgrazing. [23]

Agriculture and Instabilities

Even where overpopulation, the quality of soils, lack of rain, erosion, or salt accumulation do not pose special problems, the practice of agriculture alone may cause ecological difficulties. The most basic one is that agriculture is a simplifier of ecosystems, replacing relatively complex natural biological communities with relatively simple man-made ones based on a few strains of crops. Agricultural communities thus tend to be less stable than their natural counterparts: they are vulnerable to invasions by weeds, insect pests, and plant diseases, and they are particularly sensitive to extremes of weather and variations in climate. Historically, humanity has attempted to defend agricultural communities against the instabilities to which they are susceptible by means of vigilance and the application of "energy subsidies" (for example, by hoeing weeds, and more recently by using pesticides and mechanical cultivation). The effort has not always been successful.

Any monoculture is highly vulnerable to plant pests and diseases. An insect pest, a fungus, or a strain of bacteria can sweep through the entire plant population. A classic example of the destruction of a monoculture is provided by one of the first Green Revolutions -- the introduction of the potato into Ireland in the eighteenth century. The potato provided the basis for an increase in the Irish population from 3 million people living in poverty to 8 million living in poverty. In such situations, expansion of the food supply does not necessarily lead to an increase in the standard of living; more frequently, it leads only to more people living at the same low standard. Between 1845 and 1848, a fungal blight invaded the fields, producing one of history's great disasters -- the

[23]R. Baker, "Famine: The cost of development?"

Irish potato famine. The unstable potato ecosystem collapsed and with it the artificially augmented carrying capacity of the land. In four years of crop failures, 1.5 million people starved to death, 2 million emigrated, and millions of others underwent great suffering through semistarvation. [24] Advances in agricultural technology in the past hundred years have not resolved the ecological dilemma of agriculture; they have aggravated it. The dilemma can be summarized in this way: agriculture tries to manage ecosystems in such a way as to maximize productivity; nature "manages" ecosystems in such a way as to maximize stability. The two goals are incompatible. In short, in agriculture productivity is achieved at the expense of stability.Of course, humanity must practice agriculture to support even a fraction of the existing human population. A degree of instability in agricultural ecosystems must therefore be accepted and,

where possible, compensated for by technology. However, the trends in modern agriculture, associated in part with the urgent need to cope with unprecedented population growth and in part with the desire to maximize yields (the amount of harvest per hectare) for strictly economic reasons, are especially worrisome ecologically. The three major liabilities are:

As larger and larger land areas are given over to farming, the unexploited tracts available to serve as reservoirs of species diversity and to carry out the public service functions of natural ecosystems become smaller and fewer.

Even in parts of the world where land area under agriculture is constant or (for economic reasons) dwindling, attempts to maximize yields have led to dramatic increases in the use of pesticides and inorganic fertilizers -- increases that have far-reaching ecological consequences themselves.

The quest for high yields has led also to the replacement of myriad traditional crop varieties around the world with a few, specially bred, high-yielding strains. Areas of unprecedented size are now planted to single varieties of wheat or rice. Because of this enormous expansion of monoculture, the chances are much greater for an epidemic crop failure from insects or disease -- one that might occur over an area far greater than any crop failure in the past.

POLLUTANTS IN ECOSYSTEMS

The expansion and intensification of agriculture has been accompanied by a continuing Industrial Revolution that has multiplied many times over both the magnitude and the variety of the substances introduced into the biological environment by human beings. In the last chapter we classified these substances as either *qualitative pollutants* (synthetic substances produced and released only by human action) or *quantitative pollutants* (substances naturally present in the environment but released in significant additional amounts by human activities).

Well-known qualitative pollutants include the chlorinated hydrocarbon pesticides such as DDT, the related class of industrial chemicals called PCBS, and some herbicides. These substances are biologically active in the sense that they stimulate physiological changes. But, because organisms have had no experience with them over evolutionary time, the substances are usually not biodegradable. Indeed, some, like the pesticides kepone and mirex, are among the most stable molecules ever synthesized by chemists. Thus, they may persist in the environment for years, and even decades, after being introduced, and be transported around the globe by wind and water. Their long-term effects will be discovered only by experience.

As noted in Chapter 10, the significance of quantitative pollutants in a given situation must be judged according to whether the natural abundance of the agent is altered slightly or substantially, locally or globally, suddenly or gradually, and according to how harmful the agent is at its naturally occurring concentrations.

Concentration of Toxic Substances in Ecosystems

Nowhere is human ecological naiveté more evident than in popular assumptions about the capacity of the atmosphere, soils, rivers, and oceans to absorb pollution. Those assumptions all too often take the following form:

[24]G. L. Carefoot and E. R. Sprott, *Famine on the wind*.

if 1 liter of poison is added to I billion liters of water, then the highest concentration of poison to which anything will be exposed is about one part per billion. This might be approximately true if complete mixing by diffusion took place rapidly (which it often does not) and *if only physical systems were involved*. But because biological systems are involved, the situation is radically different. Ignorance of this point is not confined to laymen. For instance, Sir Robert Robinson, Nobel laureate in organic chemistry, made the following classic blunder. In a letter to the London *Times* (February 4, 1971) discounting the threat of leaded compounds to oceanic plankton, he began: "Neither our 'Prophets of Doom', nor the legislators who are so easily frightened by them, are particularly fond of arithmetic . . ." and then went on to do some "simple arithmetic" (as he described it) to show that the dilution of lead in the oceans would be so great that the lead would remain biologically negligible. Of course, his whole exercise completely missed the point, because of -- among other things -- the phenomenon of biological amplification.

Filter-feeding animals, for example, may concentrate poisons to levels far higher than those found in the surrounding medium. Oysters capture food by constantly filtering the water they inhabit, and they live in shallow water near the shore, where pollution is heaviest. Consequently, their bodies often contain much higher concentrations of radioactive substances or dangerous chemicals than the water in which they live. For instance, oysters have been found to accumulate up to 70,000 times the concentration of chlorinated hydrocarbon insectides that exists in their environment. [25] Food chains may also lead to concentration of toxic substances; they act as a kind of biological amplifier. The diagram of a Long Island estuary food web in Figure 4-25 shows how the concentrations of DDT and its derivatives tend to increase in food chains from one trophic level to another. That tendency is especially marked for the chlorinated hydrocarbons because of their high solubility in fatty substances and their low solubility in water. Although the clam and the mud snail are at the same trophic level, the filter-feeding clam accumulates more than half again as much DDT as the mud snail because of the difference in their food-capturing habits.

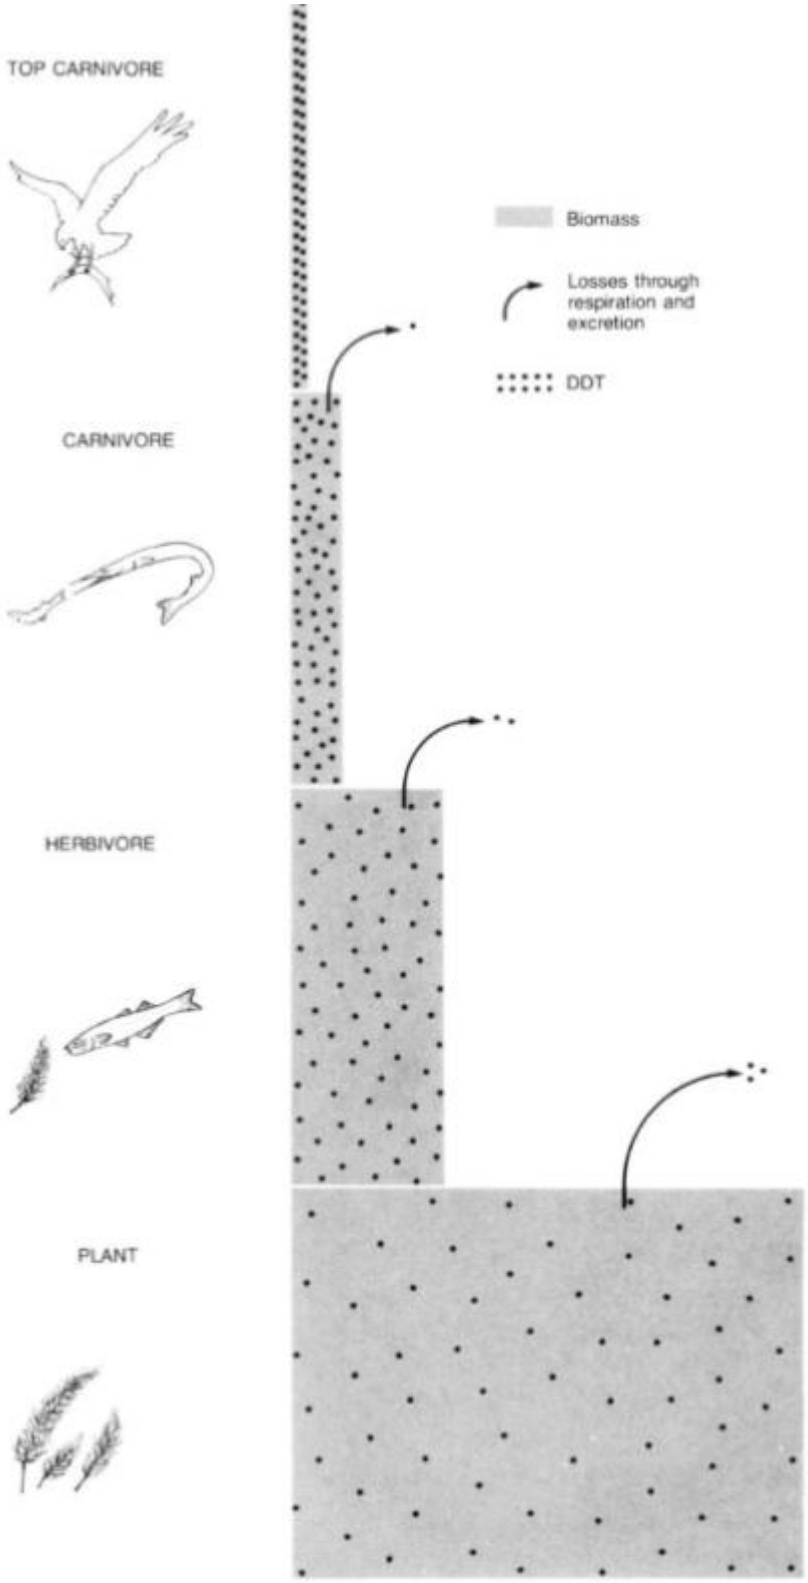
The mechanism of concentration in food chains is simple. One would expect from the second law of thermodynamics (Chapter 2) that the mass of herbivores normally is not as great as the mass of plants they feed on. With each step upward in a food chain the biomass is reduced. Energy present in the chemical bonds of organisms at one level does not all end up as bond energy at the next level, because much of the energy is degraded to heat at each step. In contrast, losses of DDT and related compounds along a food chain are small compared to the amounts that are transferred upward through the chain because they tend to be neither degraded nor eliminated from the organisms. As a result, the concentration of DDT increases at each level (Figure 11-3). Concentrations in the birds at the end of the food chain are from tens to many hundreds of times as great as in the animals farther down the chain.

Food chain concentration in aquatic environments is not as frequently observed as in terrestrial ones because of the tendency at each trophic level for the concentrations of compounds to

equilibrate between organism and water -- the equilibrium being roughly the same at all levels. Concentration will only occur if movement from level to level is fast enough to prevent the reaching of equilibrium at each level. [26]

Insecticides in Ecosystems

Besides being direct threats to human health, synthetic insecticides [27] are among society's most potent tools for



---

[25] P. A. Butler, *The significance of DDT residues in estuarine fauna*. Concentration factors (residue in organism divided by that in environment) as high as 1 million have been recorded for DDT residues in sea squirts (E. E. Kenaga, "Factors related to bioconcentration of pesticides").

[26] See, for example, R. W. Risebrough, E. Huschenbeth, S. Jensen, and J. E. Portmann, "Halogenated hydrocarbons". Technical papers providing the background for this conclusion include J. L. Hamelink, R. C. Waybrant , and R. C. Ball, "A proposal: Exchange equilibria dominate the degree chlorinated hydrocarbons are biologically magnified in lentic environments"; H. O. Sanders and J. H. Chandler, "Biological magnification of a polychlorinated biphenyl (Aroctor^{R} 1254) from water by aquatic invertebrates"; R. E. Reinert, *Accumulation of dieldrin in an alga* (*Scenedesmus obliquus*), *Daphnia magna*, and the guppy (*Poecilia reticulata*.); G. R. Harvey et al., "Observations on the distribution of chlorinated hydrocarbons" in Atlantic Ocean organisms.

[27] Insecticides are chemicals designed to kill insects, miticides are to kill mites, and herbicides are to kill weeds. All are pesticides. Pesticides are sometimes referred to as biocides; miticides are often lumped in with insecticides, as they are here. Other pesticides are used against rodents (rodenticides), roundworms (nematocides), fungi (fungicides), bacteria (antibiotics), and so on.

FIGURE 11-3

Concentration of DDT along a simple food chain. As living material is passed from one link to another, more than half of it is consumed by respiration or excreted (arrows). The losses of DDT

residue along the chain, on the other hand, are small in proportion to the amount transferred, leading to the high concentrations in carnivores. (After Woodwell, 1967.)

simplifying and thus destabilizing ecosystems (they are discussed in Box 11-1). The increase in the concentration of the most persistent of those compounds with each upward step in a food chain exposes the populations least able to survive poisoning to the highest concentrations.

There are several reasons why the organisms near the upper ends of food chains are less able to cope with the poisons than are, for example, herbivores. The first traces back again to the second law of thermodynamics. Because of the loss of available energy at each transfer, the higher a given population occurs in a food chain, the smaller that population is (everything else being equal). This means that if a poison were applied that would kill most of the predators and herbivores in an area, it would be more likely to exterminate the population of predators than the population of herbivores, simply because there would be fewer predators to begin with. Purely by chance, some members of the larger population would be more likely to survive. It is not even necessary to kill all individuals of any one species of predator to force it to extinction. If survivors were too scattered or weakened for the sexes to find one another and produce offspring, extinction would surely follow. Or, if survivors were few, loss of genetic variability might cause the population to dwindle to zero. (See also Chapter 4.)

Another reason that small populations of animals high on a food chain are more vulnerable is that smaller populations tend to have less genetic variability. Suppose, for instance, that I individual per 100,000 in each of two species of insects by chance carries a mutant gene that makes it naturally resistant to a certain pesticide. Assume that one species is a herbivore (a pest, for our purposes) and its population in a field consists of 1 million individuals, while the second species is a predator of the first, with a population of 100,000 individuals. If the field is thoroughly treated with the pesticide, killing all susceptible insects, 10 individuals of the pest species will survive, but only I of the predator species will survive, each of the survivors being naturally resistant mutants. In this oversimplified example, the consequences are obvious. The small group of resistant pest insects can quickly reproduce a large population, free from attack by its predator. But because most individuals in the replacement pest population will be resistant, the next treatment with insecticide will have

BOX 11-1 Synthetic Insecticides

The majority of synthetic insecticides belong to three groups of compounds: chlorinated hydrocarbons, organophosphates, and carbamates.

Chlorinated Hydrocarbons

Chlorinated hydrocarbons include DDT, benzene hexachloride (BHC), dieldrin, endrin, aldrin, chlordane, lindane, isodrin, toxophene, and similar compounds designed to kill insects. DDT is the most thoroughly studied of the chlorinated hydrocarbons, and much of the following discussion is based on what is known about it. In its behavior it is more or less typical of the group, although other chlorinated hydrocarbons may be more soluble in water, more toxic, less persistent, and so forth. In insects and other animals these compounds act primarily on the central nervous system in ways that are not well understood, but the effects range from hyperexcitability to death following convulsions and paralysis. There is evidence that DDT

interferes with the movements of ions through the membranes of nerve cells--movements that must occur for nerve impulses to be propagated. Effects of DDT outside the nervous system also seem linked to processes involving cell membranes, as, for instance, in the membranous energy-mobilizing apparatus of the mitochondria (the power plants of cells). [a] Chronic effects on vertebrates include infiltration of fat into heart muscle and fatty degeneration of the liver, which is often fatal. Fishes and other aquatic animals seem to be especially sensitive to chlorinated hydrocarbons. Their oxygen uptake is somehow blocked at the gills, causing death from suffocation. That chlorinated hydrocarbons apparently can influence the production of enzymes may account for their wide range of effects.Chlorinated hydrocarbons tend to be highly soluble in fats and fatty tissues. In animals this means that they may be stored at sites remote from the primary active site in the nervous system and thus rendered relatively harmless. These compounds are more toxic to insects than to mammals, primarily because they are absorbed more easily through insect cuticle than through mammalian skin. Chlorinated hydrocarbons vary greatly in their toxicity to plants. They are able, at least in experimental situations, to slow the rate of photosynthesis--almost certainly by operating on the membranes of the photosynthetic organelles (the chloroplasts). [b] Four properties make chlorinated hydrocarbons a particular threat to ecosystems:

> Chlorinated hydrocarbons have a wide range of biological activity; they are broadspectrum poisons, affecting many different organisms in many different ways. They are toxic to one degree or another to essentially all animals.
>
> They have great stability. It is not clear, however, just how long DDT persists in ecosystems. Fifty percent of the DDT sprayed in a single treatment, for example, might still be found in a field ten years later. This would not mean, however, that the other 50 percent had been degraded to biologically inactive molecules; it might only have gone elsewhere. Probably DDT (including its biologically active breakdown product DDE) has an average halflife (the time required before 50 percent has been degraded) of much more than a decade. Indeed, DDE may be virtually immortal. [c]
>
> Chlorinated hydrocarbons are very mobile. For example, the chemical properties of DDT cause it to adhere to dust particles, on which it can be blown around the world. Four different chlorinated hydrocarbons have been detected in dust filtered from the air over Barbados, apparently having been transported there across the Atlantic; [d] frog populations in unsprayed areas high in the Sierra Nevada of California are polluted with DDT. [e] Furthermore, DDT codistills with water (when water evaporates and enters the atmosphere, DDT goes with it). Chlorinated hydrocarbons thus travel in the air and in surface waters.
>
> The high solubility of chlorinated hydrocarbons in fats amounts to an affinity for organisms. These pesticides move continually from the nonliving part of the environment into living systems. To attempt to monitor DDT levels merely by testing water (as has frequently been done) is ridiculous. Water is saturated with DDT (that is, it can dissolve no more) when it has dissolved 1.2 parts per billion, but the chemical does not remain for long in water;

mountains.

it is quickly removed by any organisms that live there.

It is these four properties--an extreme range of biological activity, stability, mobility, and affinity for living systems--that cause biologists to fear that DDT and its relatives are degrading the life-support systems of our planet. If any one of the four properties was lacking, the situation would be much less serious, but in combination they pose a deadly threat.

Organophosphates

Organophosphates include parathion, EPN, malathion, Azodrin, diazinon, dichlorvos, TEPP, phosdrin, and numerous others. These poisons are descendants of the nerve gas Tabun (ethyl N-dimethylphosphoramidocyanidate), developed in Nazi Germany during World War II. The majority of them are cholinesterase inhibitors; they inactivate the enzyme responsible for breaking down a nerve "transmitter substance," acetylcholine. The result in acute cases of poisoning is a blockade of synapses (connections between nerve cells) that use acetylcholine as a transmitter--often with lethal effect. Unlike chlorinated hydrocarbons, organophosphates tend to be unstable and nonpersistent; hence, they tend not to produce chronic effects in ecosystems or to accumulate in food chains. [f] They often, however, are extraordinarily toxic. For example, the LD_{50} (dose required to kill 50 percent of a group of test animals) of TEPP when administered orally to white rats is only from 1 to a few milligrams per kilogram of body weight. [g] It is so toxic it is not marketed today.

Organophosphates inhibit other enzymes as well as cholinesterase. Indeed, some of the ones that show relatively great toxicity for insects and little toxicity for mammals do so because they poison an esterase that is more critical to the functioning of insect than of mammalian nervous systems. Malathion, which is violently poisonous to insects, is relatively nontoxic to mammals (acute oral LD50 in rats 900-5800 mg/kg) because mammalian liver and, to a lesser degree, other tissues contain the enzyme carboxyesterase, which destroys malathion. But relatively high toxicity to mammals can occur when malathion is used in combination with some other organophosphates (such as EPN) that apparently inhibit carboxyesterase. For example, in dogs one-fortieth of the LD_{50} of malathion administered with one-fiftieth of the LD_{50} of EPN killed *all* the experimental animals--a classic example of a synergistic effect. [h]

While most organophosphate pesticides produce acute poisoning, with transient loss of muscular strength and coordination due to their inhibition of cholinesterase, a few of these compounds have a delayed neurotoxic effect. For example, one organophosphate, Phosvel (leptophos), has a very low acute oral toxicity in chickens (4700 mg/kg), but after receiving doses ranging from 180 to 3000 mg/kg, which did not cause immediate symptoms, individuals developed irreversible, lethal neurological problems. The symptoms of this nerve poisoning appeared only after a delay of 8 to 13 days. Phosvel has been implicated in a kill of some 1300 water buffalo in the Nile delta in 1971, [i] and employees of a Phosvel manufacturing plant have developed delayed neurological symptoms (see Chapter 10).

Carbamates[j]

Insecticides of the carbamate group include Sevin (carbaryl), zectran, baygon, dimetilan, pyrolan, and Temik (aldicarb). Chemically, these are esters of a derivative of carbamic acid. Attention originally was called to this group of compounds in the nineteenth century because one of them, eserine (physostigmine), proved to be the active ingredient in a poisonous plant, *Physostigma venenosum*, used in trials by ordeal by West Africans. Synthetic analogues of eserine were used in medicine, but they had no insecticidal properties. Synthetics with insecticidal properties were first developed by Geigy Company in Switzerland in 1947. [k]

Like organophosphates, carbamates inhibit cholinesterase, and some have very high acute toxicity (for example, aldicarb is in the same class as TEPP) [l] They were introduced in many instances as substitutes for chlorinated hydrocarbons when insects developed resistance to the latter. They are quite selective in their action, as some insects are highly susceptible to these poisons and others are quite resistant. They also show variation in their degree of persistence in the environment, [m] but generally they are much less persistent than chlorinated hydrocarbons.

little effect. If dosage of the insecticide is increased, the pest species will respond by becoming more and more resistant with each generation. Not only herbivorous pests but other large populations can easily evolve such resistance; for example, resistance to DDT has developed in many mosquito populations, which has hampered malaria-control programs.

Artificial poisons tend to be much more effective against predators and parasites than against herbivores for another reason--the long coevolutionary experience herbivores have with plant poisons. Herbivores that were not adept at circumventing poisons are mostly long since extinct. Small wonder that the evolutionary "winners" now being assaulted by mankind's poisons have so often managed to evolve resistance to them rapidly. Indeed, applications of pesticides often lead to *higher* concentrations of pests rather than lower, either because they directly poison the natural enemies of the pest or because they indirectly decrease the efficiency of those enemies as control agents. They accomplish the latter in several ways. One is through the very success of the pesticide in reducing the target pest population. This may deprive the pest's natural enemies of

their prey and thus reduce the predator or parasite population to a level where it is ineffective as a control when the pest population resurges. Similarly, the natural enemies of the pest may be decimated if the pesticide kills off another species preyed on by the same predator or parasite. Such an alternate host may be necessary to keep the predator population going all year round; if it is destroyed, the natural control is destroyed also. [28]

There are, of course, many actual cases in which differential kill of predators has released some prey species from their natural restraints. It is fair to say, for instance, that mites, as pests, are a creation of the pesticide industry. Careless overuse of DDT and other pesticides has promoted many of these little insectlike relatives of spiders to pest status by killing the insects that previously kept them under control. The emergence of the European red mite as a major pest in apple orchards followed the use of DDT to control the codling moth. [29] This is only one of the many examples in which pesticides intended for one pest have led others to flourish. A common response by the pesticide industry to such situations is to recommend the use of heavier doses of the original pesticide or to develop more potent poisons, which then create another array of pollution problems. [30]

In such cases one or more pests were being held in check by natural biological controls, which were upset by the introduction of the chemical. That so many organisms can be "promoted" to pest status by the killing of predators and parasites with pesticides is itself a powerful testimonial for reliance on biological controls, instead. Such controls are constantly at work suppressing potential pests at no economic cost.

Effects of Insecticides on Nontarget Organisms

Of all the synthetic organic pesticides, probably more is known about DDT than any other. It is the oldest and most widely used chlorinated hydrocarbon insecticide. Although there has been an almost total ban on the use of DDT in the United States since 1972 and its use has been prohibited in some other countries, worldwide use in the mid-1970s was probably as great as in the mid-1960s. [31] DDT is found everywhere--not only where it has been applied, but all over the Earth. [32]

Virtually every kind of animal on Earth has been exposed to it. As noted earlier (Table 10-6), concentrations in the fat deposits of people in the United States average about 12 ppm, and in the people of India and Israel they are much higher. More startling and significant in some ways has been the discovery of DDT

See also the discussion of the Volterra principle in chapter 22 of J. Roughgarden's *Theory of population genetics and evolutionary ecology, an introduction*, for another reason why pest control programs may lead to bigger pest problems.

[29] For a detailed discussion of the role of pesticides and predators in the control of plant-eating mites, see C. B. Huffaker, M. van den Vrie, and J. A. McMurtry , "The ecology of tetranychid mites and their natural control"; J. A. McMurtry, C. B. Huffaker, and M. van den Vrie, "Ecology of tetranychid mites and their natural enemies: A review".

[30]Numerous examples of promotion of nonpests to pests by pesticide misuse are given in Paul De Bach, *Biological control by natural enemies*.

[31]Ecologist G. M. Woodwell, quoted in the *New York Times*, February 14, 1975. World use in 1973 was estimated at about 150,000 metric tons.

[32]T. J. Peterle, "DDT in Antarctic snow", *Nature*, vol. 224, p. 620 (November 8, 1969). His estimates of the quantity of DDT are now thought to be much too high (R. Risebrough, personal communication.)

FIGURE 11-4
A crushed egg in the nest of a brown pelican off the California coast. This egg had such a thin shell that the weight of the nesting parent's body destroyed it. The concentration of DDE in the eggs of this 300-pair colony reached 2500 parts per million; no eggs hatched. (Photo by Joseph R. Jehl, Jr.)

residues in the fat deposits of Eskimos and in those of Antarctic penguins and seals. [33] Seals from the east coast of Scotland have been found to have concentrations of DDT as great as 23 ppm in their blubber, and both DDT and DDE contaminate fishes living 2500 meters deep in the ocean. [34] Pesticide pollution is truly a worldwide problem.

The impact of chlorinated hydrocarbons on birds. Because DDT breaks down so slowly, it lasts for decades in soils. For instance, in the Long Island estuary studied by Woodwell and his colleagues (Figure 4-25), the marsh had been sprayed for twenty years for mosquito control. Up to 32 pounds per acre of DDT were found in the upper layer of mud there. Such concentrations in U.S. soils are not unusual. As a result of the progressive concentration of DDT as it moves up food chains, the danger to the lives and reproductive capacities of fish-eating birds became extreme in the 1960s. Nesting failures among bald eagles attributable to DDT reached proportions that brought the survival of the species into severe jeopardy. In addition, reproductive difficulties in populations of such diverse birds as the peregrine falcon and the brown pelican have been traced to residues of DDT. DDE, a breakdown product of DDT, interferes with the birds' ability to transport calcium, which results in their laying eggs whose shells are so thin that they are crushed by the weight of the incubating parents (Figure 11-4). Similar effects have been caused experimentally by polychlorinated biphenyls (PCBs), which are chlorinated hydrocarbons used extensively in industry and which are closely related to the insecticides, as well as by mercury compounds. [35] If they reach high enough levels in the environment they could cause problems for bird populations.

The evidence against DDT in the case of birds' eggs is now overwhelming. [36] Studies have been made of the thickness of the eggshells of raptorial birds in museum collections. Among the eggs of those species investigated that feed high on food chains, there was in virtually all

[36] See, for example, J. L. Lincer, "DDE-induced eggshell-thinning in the American kestrel: A comparison of the field situation and laboratory results".

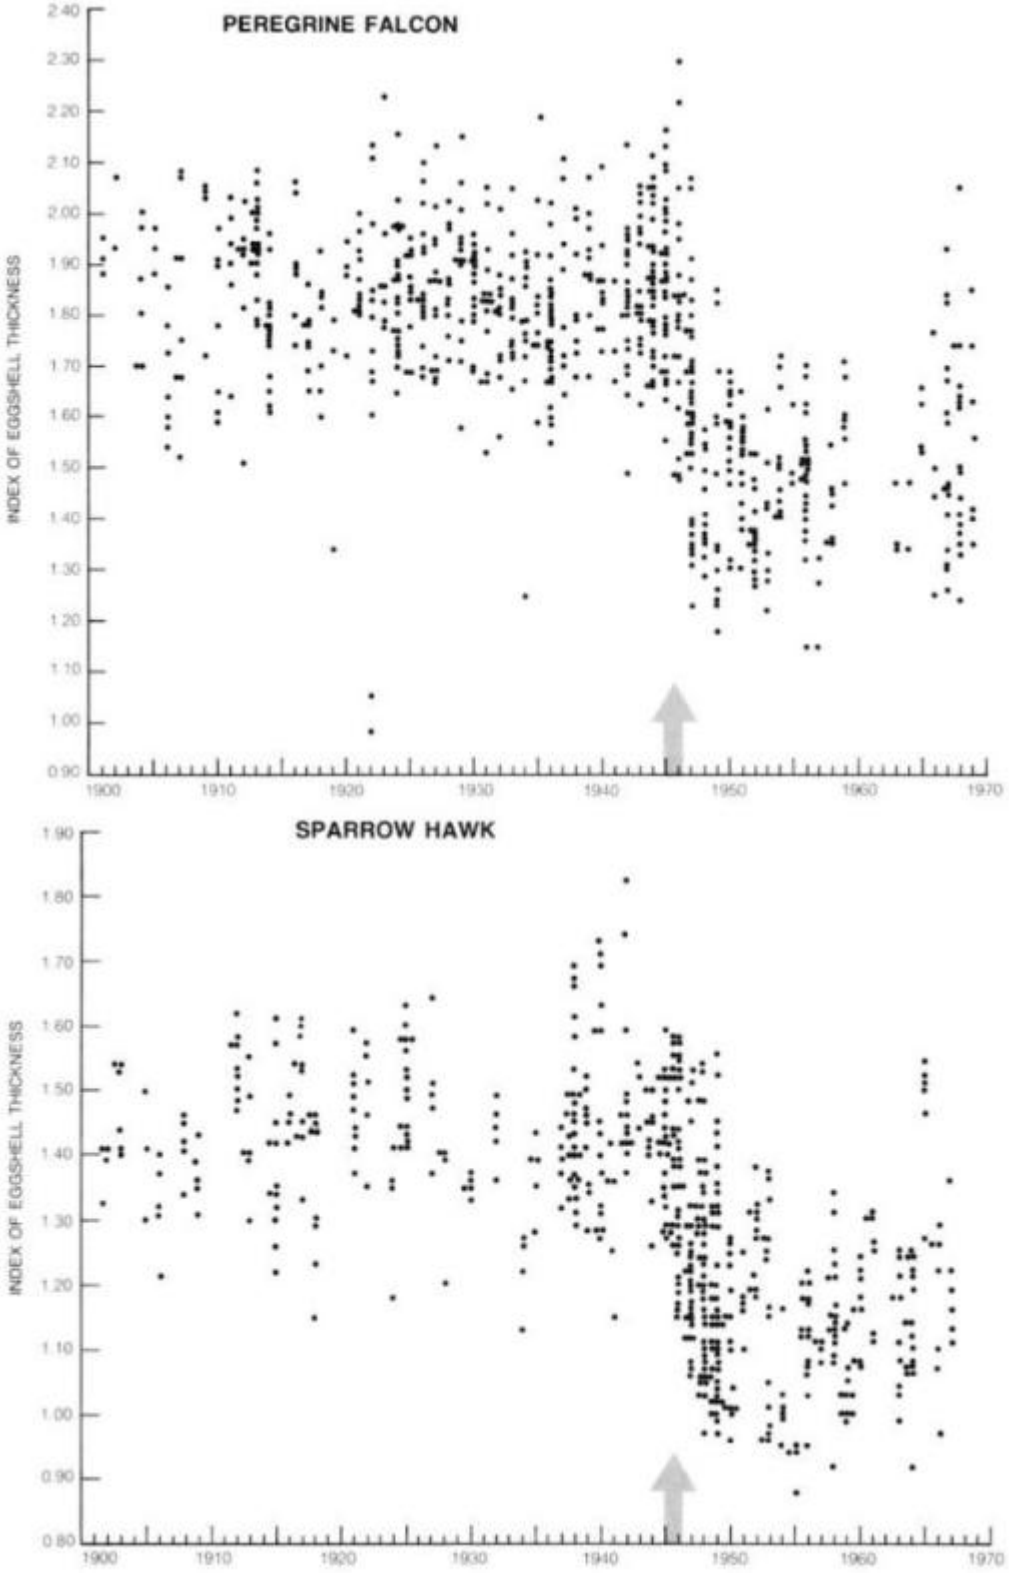

FIGURE 11-5

Changes in the thickness of the eggshells of the peregrine falcon and the sparrow hawk in Britain. Arrows indicate the first widespread use of DDT. (After Ratcliffe, 1970.)

cases a sharp decrease in the thickness of shells between 1945 and 1947, when DDT was generally introduced (Figure 11-5). DDT has been directly implicated in eggshell thinning as early as 1948. [37] In the United Kingdom a strong correlation has also been shown between the level of chlorinated-hydrocarbon contamination in various geographical regions and the thickness of eggshells of peregrine falcons, sparrow hawks, and golden eagles nesting in those regions. The exceptions make the case even more convincing. The shells of one Florida population of bald eagles first thinned in 1943, not between 1945 and 1947. Investigations disclosed that that population lived in a county where large-scale DDT testing took place in 1943. One pair of peregrines on the coast of California was an exception to the general rule of nesting failure. Examination of their nests revealed that they were feeding inland on mourning doves. Mourning doves are herbivores; therefore the peregrines were feeding much lower in the food chain than if they had been feeding on fish-eating seabirds. They picked up less DDT and were therefore able to reproduce successfully.

Experimental feedings of DDT to mallard ducks, American sparrow hawks, and Japanese quail all produced thin eggshells and reduced hatch rates. DDE, a widely distributed, stable breakdown product of DDT, has also been shown to reduce the thickness of mallard eggshells and to reduce hatchability. Sensitivity to DDE varies greatly from species to species. Brown pelicans, cormorants, and raptors show high sensitivity; ducks, gulls, and ringdoves, moderate sensitivity; and quail, chickens, and Bengalese finches, low sensitivity.

At one time it was thought that the thin eggshell phenomenon was produced by alterations in estrogen levels, which are involved in the storage of calcium in birds. However, biologist D. B. Peakall of Cornell University did a series of experiments in which DDE was injected into ringdoves shortly before they laid eggs. The eggs, when laid, had thin shells. The DDE greatly reduced the activity of carbonic anhydrase, an enzyme that plays a critical role in providing calcium for eggshell production. It is now thought that inhibition of that enzyme and ATPases involved in transporting calcium from blood to eggshell is the basic mechanism that produces the thinning. [38]

Dieldrin injected shortly before eggs are laid does not cause thinning of the eggshells. It and other chlorinated hydrocarbons (especially PCBS) do, however, lower the estrogen level, which in turn delays breeding. DDT does not have as great an estrogen effect as dieldrin, nor is it apparently as potent an inducer of liver enzymes. Late breeding is an important component of observed declines in the numbers of predatory birds, since breeding is normally timed to coincide with optimal food supplies for the young. Interestingly, some of the most spectacular declines in the populations of these birds occurred years after thin eggshells first appeared-about the time that dieldrin was introduced.

There was, fortunately, a steady decrease in the amount of DDT used in the United States during the 1960s, use at the end of the decade being on the order of 25 percent what it was at the start. [39] At the end of 1972 its use was almost totally banned. Few reductions in DDT (or other organochlorine pesticides) residues were reported before 1970, [40] but by 1974 a steady decline in the concentrations of DDT and its breakdown products DDD and DDE had been detected in migratory songbirds and in the eggs of brown pelicans. [41]

In the United Kingdom, where use of organochlorines had been restricted, investigators were able to show an increase in the breeding success of Scottish golden eagles that was associated with a decline in the DDE and dieldrin content of their eggs, and they also recorded a decrease in the organochlorine content of cormorant (shag) eggs. [42]

Shell-thinning is not the only way in which DDT can affect birds. For instance, it can also influence behavior

Crabtree, "Changes in organochlorine contamination of the marine environment of eastern Britain monitored by shag eggs".

associated with migration. [43] Such effects should decrease if the use of this dangerous chemical were phased out. Thus, if the use of organochlorines declines, there seems to be every reason for optimism that the effects of those poisons on the ecosystem will abate.

The impact of chlorinated hydrocarbons on aquatic organisms. Birds are not the only organisms that have suffered from chlorinated hydrocarbons. Coho salmon in Lake Michigan, which also feed at high trophic levels, have been laying eggs that contain DDT residues. In 1968 almost 700,000 young salmon died as they absorbed the last DDT-rich drop of oil from their yolk sacs. Trout have had similar problems, and DDT has been found in such commercially important marine fishes as tuna, mackerel, and hake.

One spectacular example of the destruction of nontarget organisms by pesticides was described in detail by reporter Frank Graham, Jr., [44] who recounted the story of a great Mississippi fish kill in the early 1960s. Rough estimates gave the total loss in the four years from 1960 to 1963 as between 10 million and 15 million fishes in the lower Mississippi and its bypass, the Atchafalaya. The fishes killed included several kinds of catfish, menhaden, mullet, sea trout, drumfish, shad, and buffalo fish. The die-offs were ruinous to the local fishing industry. A thorough investigation by government (U.S. Public Health Service) and private laboratories placed the blame primarily on the highly toxic chlorinated hydrocarbon insecticide endrin and one of its derivatives. They were found not only in the blood and tissues of dying fishes and water birds but also in the mud in areas where fishes were dying. In experiments, extracts made

both from the mud and from the tissues of dying fishes killed healthy fishes. It was found that fish kills were greatest in 1960 and 1963, when endrin was used commonly to treat cotton and cane crops in the lower Mississippi valley, and that fish kills were smallest in 1961 and 1962, when very little endrin was used.

The Public Health Service found that runoff from agricultural lands following dusting and spraying was one major source of endrin. The other source was the Memphis plant of the Velsicol Chemical Corporation; waste endrin from the manufacturing process was getting into the river. Graham described the reaction of the Velsicol Corporation:

"Velsicol, under fire, shot back. Bernard Lorant, the company's vice-president in charge of research, issued strong denials. In a statement to the press, he said that endrin had nothing to do with the Mississippi fish kill, that the symptoms of the dying fish were not those of endrin poisoning, and that Velsicol's test proved that the fish had died of dropsy." Unfortunately for the Velsicol defense, dropsy happens to be a disease that is never *epidemic* in fishes. [45]

At a May 1964 conference in New Orleans on the Mississippi fish kill, [46] a theme promoted by the pesticide industry was that only communist sympathizers would criticize the extravagant way pesticides are used. Their approach was exemplified by a statement made well before the conference by Parke C. Brinkley, then president of the National Agricultural Chemicals Association: "Two of the biggest battles in this war [against communism] are the battle against starvation and the battle against disease. No two things make people more ripe for Communism. The most effective tool in the hands of the farmer and in the hands of the public health official as they fight these battles is pesticides." [47] This kind of response is found all too often in industries whose products are found to be dangerous. Finding ways to avoid the introduction and wide deployment of such products is a great social challenge. Once a great deal of money is committed to them, their producers tend to defend them vigorously, regardless of the risks to themselves or society (see our discussion of ozone depletion below).

In June 1969 a vast fish kill occurred in the Rhine River. Preliminary investigations indicated that containers holding at least 90 kilograms of the chlorinated hydrocarbon insecticide Endosulfan, which had dropped off a barge, were responsible. The increase in public

[47] Ibid, p. 130.

understanding between 1964 and 1969 of the ecological dangers of pesticides was perhaps indicated by the refreshing absence on that occasion of comments from the pesticide industry about either dropsy or Communists.

Some of the most devastating effects of pesticides in aquatic systems come from releases in manufacture and transport. Just as the Velsicol plant appears to have been a major source of endrin in the Mississippi, so wastes from the Montrose Chemical plant in Los Angeles County, the sole producer of DDT in the United States, appear to have been the major source of residual DDT concentrations in organisms in the coastal waters of California in 1969-70. [48] Sand crabs (*Emerita analoga*) near the sewage outfall carrying the Montrose discharge showed DDT concentrations over 45 times as great as they did near major agricultural drainage areas. This is encouraging, since measures to prevent accidental releases from factories are much more readily devised than measures to prevent the movement of pesticides from the fields where they are applied.

Another example will illustrate how complex, subtle, and far-reaching the effects of pesticide pollution may be. Ecologist L. B. Slobodkin, of the State University of New York, has described a plan to block the seaward ends of lochs in western Scotland and use them as ponds for raising fishes. [49] One of the problems was to find ways to raise the young fishes in the laboratory so they could be "planted" in the ponds. It was discovered that newly hatched brine shrimp would serve as a satisfactory food for the kinds of fishes that would be raised. The shrimp could be obtained from brine-shrimp eggs gathered commercially in the United States and sold to tropicalfish fanciers for feeding young tropical fishes. The supplies came from two places: San Francisco Bay and the Great Salt Lake. But sufficient eggs for the project could no longer be obtained from San Francisco Bay because of the demands of local aquarists and because large areas of former brine shrimp habitat had been transformed into residential subdivisions. Unfortunately, the Utah supply was of no use to the project either, because brine shrimp hatched from Utah eggs killed the young fishes in the United Kingdom. The Utah shrimp had absorbed the insecticides that drained into the Great Salt Lake from surrounding farmlands. Thus, insecticide pollution in Utah hampered fish production in Scotland!

The list of nontarget animals affected by insecticides is now of encyclopedic proportions. The amazing diversity of organisms involved, besides many beneficial insects, includes robins, amphipods, planarians, whitefish, earthworms, old-squaw ducks, warblers, rabbits, quail, lake trout, mosquito fish, bluegills, foxes, oppossums, mice, ospreys, muskrats, pheasants, turkeys, gulls, fiddler crabs, salmon, frogs, toads, snakes, big-game mammals, and various plants. Poisoning of these or any other organisms, of course, always affects the ecosystems in which they function. [50]

Insecticides, planken, and marine food chain. The effects of insecticides in water are not confined to aquatic animals. Perhaps the most disturbing ecological news of 1968 was contained in the short paper "DDT reduces photosynthesis by marine phytoplankton." The author, environmental scientist Charles F. Wurster of the State University of New York, reported that DDT reduced photosynthesis in both experimental cultures and natural communities of marine phytoplankton (such as algae and diatoms), the tiny green plants that float free in the waters of the oceans. Effects were noted at DDT concentrations of only a few parts per billion, quantities

commonly suspended in waters near land sites treated with DDT. Water at a distance from treatment sites, however, ordinarily has DDT concentrations averaging less than one part per billion.

Similar results have been confirmed for DDT, dieldrin, and the related chlorinated hydrocarbon pollutants, PCBS. Dieldrin has been shown not only to inhibit growth in dinoflagellates but to cause cell disintegration at concentrations of 100 ppb. [51] Moreover, the size reductions persisted for several generations after removal from

[48] Robin Burnett, "DDT residues: Distribution of concentrations in Emerita analoga (Stimpson) along coastal California".

[49] Aspects of the future of ecology.

[50] See D. Pimentel, "Ecological effects of pesticides on non-target species", and O. B. Cope, "Interactions between pesticides and wildlife".

[51] For example, J. L. Mosser, N. S. Fisher, T. Teng and C. F. Wurster, "Polychlorinated biphenyls: Toxicity to certain phytoplankters"; C. D. Powers ; R. G. Rowland; and C. F. Wurster, "Dieldrin-induced destruction of marine algal cells with concomitant decrease in size of survivors and their progeny".

dieldrin exposure. The vulnerability of phytoplankters to chlorinated hydrocarbons varies with environmental factors such as temperature, light intensity, and interspecific competition, as well as with geographical location. [52] Recent work has indicated that it is not the photosynthetic process of the phytoplankton that is affected by the chlorinated hydrocarbons but the rate of division of the plant cells. [53]

The possible effects of DDT on phytoplankton in nature are difficult to evaluate. Phytoplankton are the primary producers responsible for most of the food taken from the sea. If photosynthesis by marine phytoplankton were significantly reduced, the amount of life in the seas would be reduced; if marine photosynthesis ceased, virtually all sea life would die. But there is no sign that chlorinated hydrocarbons would ever reach a level in the marine environment that would pose any threat to the phytoplankton community as a whole. In response to chlorinated-hydrocarbon pollution, significant qualitative changes in the phytoplankton community seem more probable than large quantitative changes. Phytoplankton populations are differentially susceptible to chlorinated hydrocarbons; even extremely low concentrations might result in shifts of dominance, leading to huge blooms of one or a few species. Indeed, changes in dominance relations have been recorded at chlorinated-hydrocarbon concentrations that had no detectable effect on singlespecies cultures. [54] Such shifts could, in turn, produce serious consequences throughout the oceanic food webs.

One possibility is that phytoplankton less acceptable to large herbivores would dominate, so that larger animals would be affected. This shortening of food chains might leave only microscopic plants and animals as sources of food from the sea. Another possibility is that phytoplankton communities near shore could become dominated by smaller species, thereby lengthening food chains and dramatically reducing the sizes of populations of fishes at the upper trophic levels. All

of this is, of course, purely speculative, especially since levels of pollution found to cause shifts in photosynthetic rates have so far been found only extremely rarely in marine environments. As use of these pollutants declines, this once seemingly serious threat to the oceans may prove to be a nonproblem.

Similarly, the problems besetting inland waters could be aggravated by the effects of DDT on freshwater phytoplankton. On the other hand, DDT or other insecticides may actually cause phytoplankton blooms because zooplankters, which normally limit the phytoplankters by grazing on them, may be even more susceptible to the pesticides. [55] As C. F. Wurster wrote, "Such effects are insidious and their cause may be obscure, yet they may be ecologically more important than the obvious, direct mortality of larger organisms that is so often reported." [55a]

Insecticides and soils. The effects of pollutants on soils are difficult to evaluate. Soils are not just collections of crushed rock; they are extraordinarily complex ecosystems. The animals of the soil are extremely numerous andvaried (Figure 11-6). In forest communities of North Carolina, for example, an estimated 300 million small invertebrates live in each hectare of soil, about 30,000 per square meter. Some 70 percent of them are mites, a group of arthropods that may eventually be found to be as diverse as insects. In a study of pasture soils in Denmark, as many as 45,000 small oligochaete worms, 10 million nematodes (roundworms), and 48,000 small arthropods (insects and mites) were found in each square meter. [56] Even more abundant are the microflora of the soil. More than a million bacteria of one type may be found in a gram (0.035 ounce) of forest soil, as well as almost 100,000 yeast cells and about 50,000 bits of fungus mycelium. A gram of fertile agricultural soil has yielded over 2.5 billion bacteria, 400,000 fungi, 50,000 algae, and 30,000 protozoa.

In most natural situations, the plants, animals, and microorganisms of the soil are absolutely essential for its fertility. The roles some of those organisms play in the ecology of soil were indicated in our discussion of the

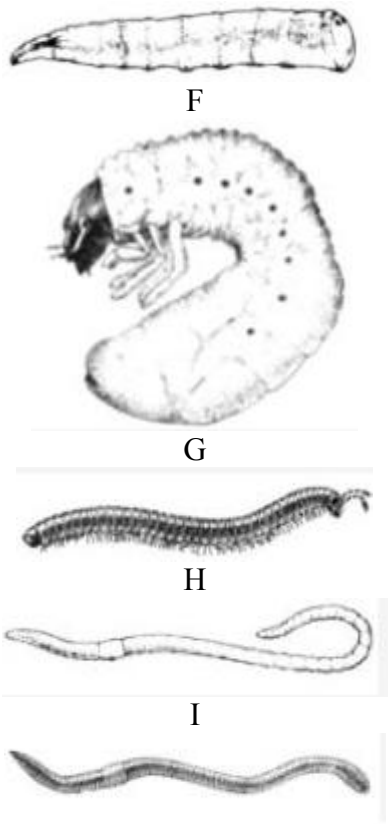

FIGURE 11-6 Nine soil-dwelling animals representative of groups that are the chief consumers of plant debris and are primarily responsible for the fertility of the soil. Seven of them belong to the phylum Arthropoda; they are (A) the wood louse, a crustacean; (B) the oribatid mite, an arachnid; (C) a termite, (D) a springtail, (E) a fly larva, and (F) a beetle larva, all insects; and (G) a millipede, a myriapod. The other two are worms of the phylum Annelida, (H) an enchytraeid worm; and (I) the common earthworm, the largest animal in the community. (From Edwards, 1969.)

nitrogen cycle (Chapter 3). The beneficial effects of earthworms are well known, but most people are unaware of the myriad other complex (and in many cases still poorly understood) ecological relationships within the soil that make it suitable for the growth of oak trees, sagebrush, corn, or any other plants. The soil contains microorganisms that are responsible for the conversion of nitrogen, phosphorus, and sulfur to forms available to the plants. And many trees have been found to depend on associations with fungi. The fungi get carbohydrates and other essential substances from the roots, and the rootfungus complex is able to extract from the soil minerals that could not be extracted by the root alone. Such mycorrhizal associations are just beginning to be understood, but it is clear that in many areas the visible plant community would be drastically altered if the mycorrhizal fungi were absent from the soil.

Recognizing, as they do, that most of the complex physical and chemical processes responsible for soil fertility are dependent upon soil organisms, environmental biologists are opposed to the continuing treatment of soils with heavy dosages of deadly and persistent poisons. Consider, for instance, a study of the persistence of ten different chlorinated hydrocarbons in a sandy loam soil at an experimental station. Table 11-1 summarizes the results, which, because of the conditions

of the study, may be close to the upper limits for persistence. Half of these insecticides had more than one-third of the amounts applied remaining in the soil fourteen or more years after treatment. Under normal agricultural conditions, chlorinated hydrocarbons seem to persist for three

to five years, whereas organophosphates and carbamates are gone in one to three months or less.

Considerable evidence already exists that the use of insecticides may reduce soil fertility, especially in woodland soils, which are subject to spraying but not artificial cultivation. Populations of earthworms, soil mites, and insects are dramatically changed, and they in turn affect the soil fungi, which are their principal food. Even if bacteria were not affected directly, there is no question that the general effects on the soil ecosystem would carry over to them and to other microorganisms. But it would be unwarranted to assume that the bacteria were not directly affected. It is known that a few microorganisms can degrade DDT to DDD under the proper conditions; a few can degrade dieldrin to aldrin and several other breakdown products of unknown toxicity. Our ignorance of the interactions of insecticides, herbicides (discussed later in this chapter), and other environmental poisons with soil microorganisms is immense.

Agriculture, Ecology, and Pest Control

Pest-control, especially insect-pest control, in agriculture today is an ecological disaster. Agronomists understandably breed out of plants some of their natural chemical defenses against the pests. Various herbivore poisons also poison people and most taste unpleasant, although some spices, which are used in small quantities, are produced by plants as pesticides. Farmers

plant crops in tight, simple monocultures, inviting pest outbreaks, to which they then respond with synthetic pesticides, often killing a higher proportion of some nontarget populations than of the target population of pests. Because synthetic pesticides, whether intended for pest animals or pest plants, have toxic effects on so many nontarget organisms, they are more accurately called *biocides*. And, because those nontarget populations often include predators and parasites of pests or potential pests, the pesticides often make pest problems worse.

Pesticides and crop losses. There are a few signs that ecologically sound agricultural practices may eventually be adopted, but so far the general trend has been in the opposite direction. The percentage of crop losses to insects in the United States seems not to have been reduced since 1945, despite the enormously increased use of powerful pesticides. In 1948, William Vogt noted in his book *Road to survival* [57] that "one-tenth of all crop plants are destroyed by insects in the U.S. every year." Vogt based his comment on statistics published by the U.S. Department of Agriculture. Georg Borgstrom, also using Department of Agriculture figures, observed that crop losses due to insects in the 1960s amounted to the yield from about one-fifth of the total acreage, or about one-sixth of the cash value of the total crop production in the United States [58] When the storage-loss component was subtracted, the field losses amounted to slightly more than one-tenth of total production -- about the same as 1948. The President's Science Advisory Committee panel on the World Food Problem estimated insect losses in the field during the 1950s as between 4 and 14 percent, depending on the crop.

In 1948, according to zoologist Robert L. Rudd of the University of California, DDT, benzene hexachloride, and lead arsenate were the only insecticides of any significance used. [59] By 1958, production of DDT and other chlorinated hydrocarbon insecticides (some of which was exported) in the United States amounted to nearly 12 times the 1948 production of DDT. Overall, pesticide usage in the United States more than doubled between 1960 and 1970, with about 500 million kilograms being used in 1972. [60] Rudd pointed out that it is difficult to get accurate estimates of pest losses and that standards of pest damage have changed through time. [61] Nevertheless, the consistency of estimates of losses caused by pests between the 1940s and 1960s was rather striking. Indeed, since 1965 the percentages of many major crops lost to pests may have been *rising*. [62] Thus, despite huge inputs of biocides, insects and diseases have been claiming a constant or growing share of the American farmers' greatly increased agricultural production.

[61] Pesticides.
[62] See D. Pimentel, "Extent of pesticide use, food supply, and pollution"; and E. Groth, III, "Increasing the harvest".

What proportion of that increased production can be attributed to the use of synthetic pesticides? Certainly not as much as the pesticide industry would like us to believe, but synthetic pesticides

may play a more significant role than is indicated in those rather dismal percentage-loss figures. High-yield strains of crops, heavily fertilized, probably require more protection per acre than lower-yield strains. That is, one might expect even greater percentages of some crops to be lost to pests today if we were still using the control techniques of 1940.

But on others the use of synthetic pesticides has decreased crop yields. According to University of California entomologist Robert van den Bosch (one of the nation's outstanding insect ecologists and an expert on ecologically sound control measures), in some California cotton fields harvests *increase* when pesticides are withdrawn. Pest problems on that state's important citrus crops are now about 3 times as severe as they were in the 1940s. [63] Ten percent of the world's insecticide load is applied to 5.7 million hectares of irrigated California land, and the state is rapidly becoming an insecticide disaster area. Of the 25 most serious insect pests in the state (each causing more than $1 million in damage), about 85 percent are resistant to one or more insecticides and all are involved in pesticide-aggravated problems -that is, they commonly have resurged following pesticide application, or they were not pests until insecticides changed the ecological situation, or pesticides applied to control them engendered outbreaks of other pests. [64]

Uncertainties about losses relative to the intensity of today's control practices make it difficult to evaluate the success of these practices, even ignoring the key questions of the undesirable side effects of pesticides or whether alternative strategies adopted decades ago would have provided superior control. [65] Could, for instance, similar or greater yields have been achieved since World War II with control methods that were more ecologically sophisticated than current pesticide practices? It is the opinion of systems ecologist K. E. F. Watt of the University of California that, when measured against successful biological and integrated control programs, "most pesticide projects have been failures." It is worth noting here that the Chinese have independently arrived at the same conclusion and have been actively developing other modes of pest control. [65a] We are convinced that the pest-control procedures in use in the 1950s and 1960s will eventually be seen as one of humanity's most tragic blunders and that when the total accounting is done, it will reveal that other methods of control would have provided higher yields at less direct cost and with fewer deleterious consequences for human beings.

Case histories of insecticide failures. Pesticides, especially the persistent ones, simplify the ecosystems to which they are applied and those into which they are transported by wind and water. The results of direct application are all too often the same: pests are freed from natural restraints. A pest, at first seemingly controlled, is soon back in even larger numbers than before. This destabilizing effect is so common that it is often cited in the scientific literature as evidence that ecosystem simplification leads to instability. Unfortunately, things do not end there in agricultural practice, and higher doses of pesticides are applied, thus aggravating the situation still further.

The history of attempts to control cotton pests in the coastal Cañete Valley of Peru has been reported by entomologist Ray F. Smith of the University of California. Against the advice of entomologists who recommended the use of cultural-control methods (such as destroying weeds which harbor pests) and inorganic and botanical insecticides, synthetic organic pesticides were

widely introduced in that valley in 1949. At first the use of the pesticides, principally the chlorinated hydrocarbons DDT, BHC, and toxaphene, was very successful.

[63]Information on the California situation from R. van den Bosch, *Bug bomb* (manuscript in preparation) and seminar, Stanford University, May 3, 1976.

[64]R. T. Luck, R. van den Bosch, and R. Garcia, Chemical insect control: A troubled pest management strategy, *Bioscience*, in press.

[65]A key recommendation of the *Report of the executive committee, Study on problems of pest control* National Academy of Sciences, Washington, D.C., 1976, was that research to resolve this uncertainty have top priority. It should have been done years before, but the vested interests of the agricultural chemicals industry and the pro-pesticide attitudes of the U.S. Department of Agriculture prevented it.

[65a]National Academy of Sciences, *Insect control in China: Trip report of the Committee on Scholarly Communication with the People's Republic of China, Insect Control Delegations*, NAS, Washington, D.C., 1976. See also Robert L. Metcalf, "China unleashes its ducks", *Environment*, vol. 18, no. 9 (November 1976), pp. 14-17.

Cotton yields increased from 494 kilograms per hectare (440 lbs/acre) in 1950 to 728 kilograms per hectare (648 lbs/acre) in 1954. The cotton farmers concluded that if more pesticide were applied, more cotton would grow. Insecticides "were applied like a blanket over the entire valley. Trees were cut down to make it easier for the airplanes to treat the fields. The birds that nested in these trees disappeared. Other beneficial animal forms, such as insect parasites and predators, disappeared. As the years went by, the number of treatments was increased; also, each year the treatments were started earlier because of the earlier attacks of the pests." [66]

Trouble started in 1952, when BHC proved no longer to be effective against aphids. In 1954 toxaphene failed against the tobacco leafworm. Boll weevil infestation reached extremely high levels in 1955/ 1956, and at least six new pests had appeared, pests that were not found in similar nearby valleys that had not been sprayed with organic pesticides. In addition, the numbers of an old pest, larvae of the moth *Heliothis virescens*, exploded to new heights, and showed a high level of DDT-resistance. Synthetic organic phosphates were substituted for the chlorinated hydrocarbons, and the interval between treatments was shortened from one or two weeks down to three days. In 1955/ 1956, cotton yields dropped to 332 kilograms per hectare, despite the tremendous amounts of insecticide applied. Economic disaster overtook the valley. In 1957 an ecologically rational integratedcontrol program was initiated, in which biological, cultural, and chemical controls were combined. Conditions improved immensely, and yields rose to new highs.

This example should not be taken to mean that ecologically unsound pesticide programs have been instituted only in other places and in former times. Many examples can be cited of mistakes made here in the United States. For example, in both California and Arizona, profit margins have been dropping for cotton farmers because of insect attacks and the rising costs of chemical pesticide applications. In an attempt to evaluate the control measures used by agriculturalists, biologists uncovered some astounding information. The programs designed to control cotton

pests in those states were reviewed by Kevin Shea, scientific director of the U.S.-based Committee for Environmental Information. [67] Shea reported, "controlled experiments on small plots suggest that cotton growers in California may have spent thousands of dollars to fight an insect, the lygus bug, that has no appreciable effect on the final production per acre." Reduction of the number of lygus bugs per acre *did not lead to increased yields*, apparently because the bugs fed on "surplus" squares (flower buds) of cotton, which would not ripen in any case. Spraying for lygus bugs in mid-season with some pesticides not only did not help yields, but lowered them by killing the insect predators of the bollworm, which caused outbreaks of bollworms and other pest caterpillars. In fact, by the mid-1970s the bollworm had virtually disappeared as a pest of cotton in the San Joaquin Valley. This had occurred because of adjustments in the lygus spray program (that is, sprays have been limited to restricted acreages in the early part of the season). [68]

Most disturbing of all is the Azodrin story. Azodrin is a broad-spectrum organophosphate insecticide manufactured by the Shell Chemical Company (a subsidiary of the Shell Oil Company). Azodrin kills most of the insect populations in a field, but like other organophosphates (and unlike the cholorinated hydrocarbons) it is not persistent. Its effects are devastating to populations of predatory insects. Therefore, when a field is reinvaded by pests, or when pest survivors make a comeback, their natural enemies are often absent, and pest-population booms may occur. Experiments by van den Bosch and his colleagues clearly indicated that, rather than controlling bollworms, Azodrin applications, through their effect on the bollworms' natural enemies, actually *increased* bollworm populations in treated fields. Figure 11-7 summarizes the experimental results.

Other Azodrin experiments, and the similar results obtained with the use of other broad-spectrum pesticides, make it clear that the control procedure, rather than helping the farmer, often has precisely the opposite effect. One might reasonably expect the pesticide manu-

[66]Quote is from R. F. Smith, The new and old in pest control, *Memorie della Reale Academia Nazionale dei Lincei* (Rome), Mimeographed, 1969. Further material on the Cañete disaster, including complete records of yields from 1943 to 1963 can be found in T. B. Barducci, Ecological consequences of pesticides used for the control of cotton insects in Cañete Valley, Peru, in *The careless technology; Ecology and international development*, M. T. Farvar and J. P. Milton, eds.

[67]Kevin P. Shea, "Cotton and chemicals".

[68]R. van den Bosch, personal communication, June 1, 1976.

facturer to withdraw the product, or at least warn customers and advise them how to avoid the disastrous effects. However, Shea wrote: " Shell Chemical Company, manufacturer of Azodrin, was aware of the University's findings through publications and from a seminar given at the Shell Research Center in Modesto. Nevertheless, the Company decided to promote the material for use on cotton pests in the San Joaquin Valley. Shell mounted a massive sales campaign. Radio, television, billboards, bumper stickers, and trade journal ads were employed to move Azodrin out of the warehouses and into the fields. Azodrin was heralded as being unmatched in

its ability to kill every major insect likely to damage cotton." The Modesto seminar was given by van den Bosch, who has said, "our own experiments indicate considerable odds against significant economic gains resulting from the use of Azodrin." [69]

Shell further has been promoting the use of Azodrin on a fixed schedule, whether pests are present or not. But fixed-schedule spraying unnecessarily damages nontarget organisms, destabilizes the agricultural ecosystem, and creates pest problems that otherwise would not arise. Aside from enhancing those effects, such programs, of course, promote the development of resistant strains of pests and the destruction of natural enemies. This guarantees the "need" for heavier and heavier doses of Azodrin. As one Azodrin advertisement put it, "even if an overpowering migration (*sic*) develops, the flexibility of Azodrin lets you regain control fast. Just increase the dosage according to label recommendations." The pesticide manufacturer is clearly the only beneficiary of such practices. It is ironic that Shell in 1975 was heavily promoting Azodrin in the Cañete Valley of Peru, as indicated by Figure 11-8!

A similar problem is the heavy use of pesticides in attempts to control so-called cosmetic pests -- insects whose damage to crops is limited largely or wholly to the appearance of the produce. Growers often suffer genuine economic losses from such pests because consumers have been conditioned by advertising to associate blemishfree appearance with high quality. A well documented

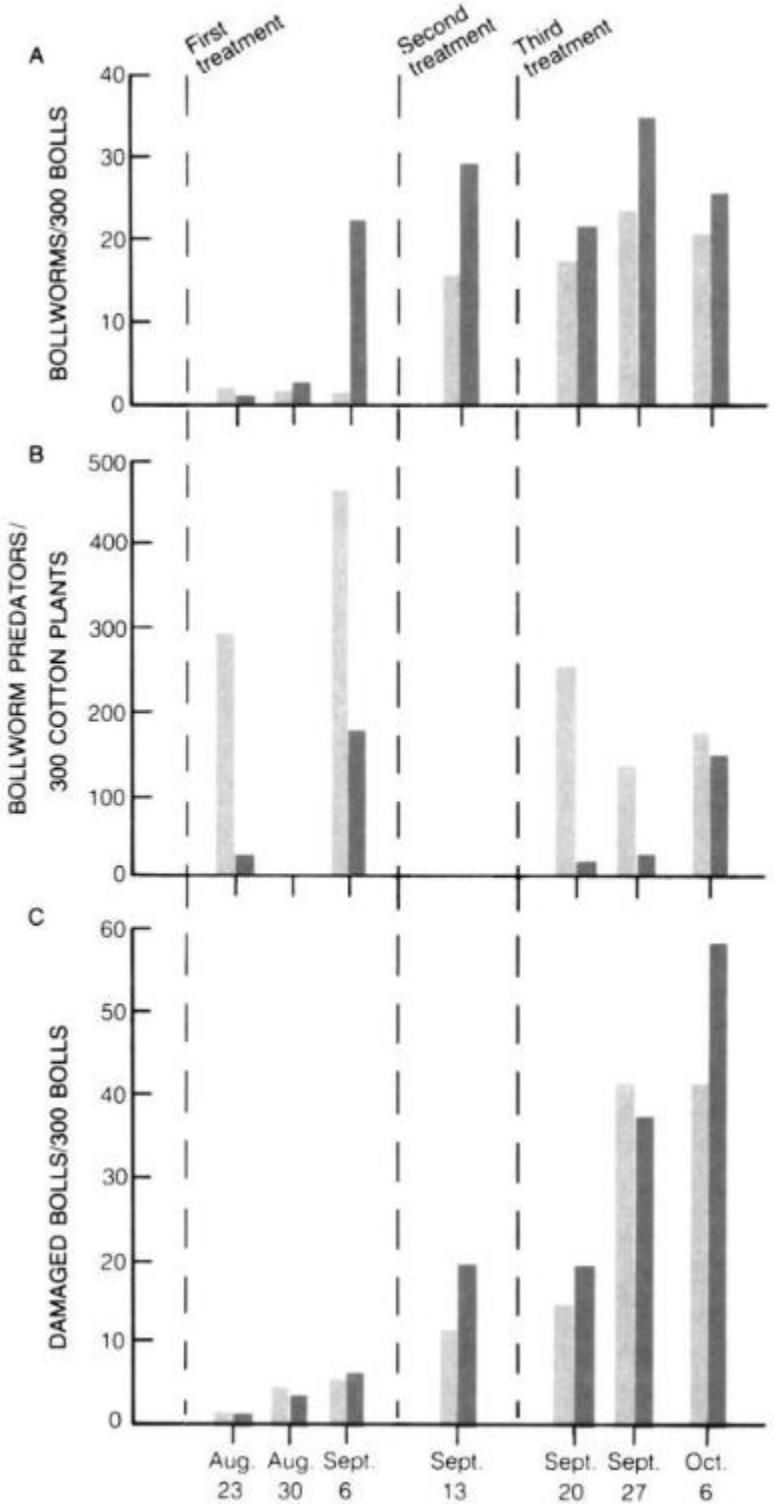

FIGURE 11-7 The results of an experiment using Azodrin to "control" bollworms. A. The number of bollworms in the untreated control plot compared with the number found in the plot treated with Azodrin. B. The number of bollworm predators in the control plot and the plot treated with Azodrin. C. The number of damaged cotton bolls in the control plot and the plot treated with Azodrin. These results indicate that Azodrin is more effective against bollworm predators than against bollworms, so the pesticide treatment increases the damage to the crop.

(Data from R. van den Bosch et al., Pest and disease control program for cotton, University of California Agricultural Experiment Station, 1968.)

[69] Van den Bosch's view of the Azodrin situation can be found in "The toxicity problem: Comments by an applied insect ecologist", in *Chemical fallout: Current resarch on persistent pesticides*, M. W. Miller and G. G. Berg , eds.

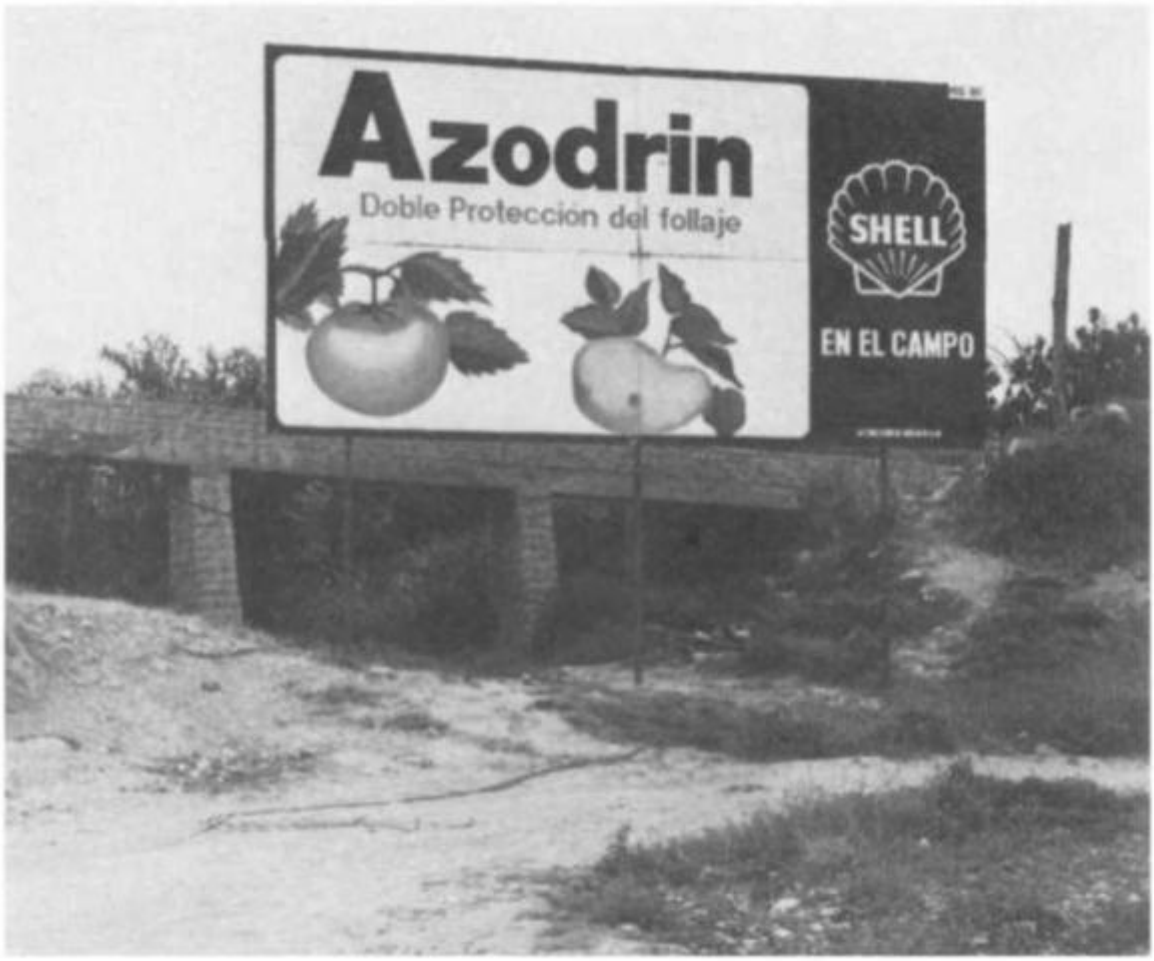

FIGURE 11-8 A sign advertising Azodrin in the Cañete Valley of Peru, January 1975. (Photo by P. R. Ehrlich.)

example of pesticide abuses in connection with cosmetic pests is the case of the citrus thrips, which scars some oranges grown in California but does not significantly influence yield or damage trees. [70]

Van den Bosch has stated that it is his conservative estimate that in California twice as much insecticide is used as is actually needed. [71] Since the insecticide market in California probably amounts to some $125 million to $150 million a year, one can understand the reluctance of the petrochemical industry to see a sensible pattern of use emerge that would reduce that market by at least 50 percent.

Pesticides and the Department of Agriculture. It would be unfair to blame the petrochemical industry alone for the misuse of pesticides. The U.S. Department of Agriculture (USDA) has also contributed heavily to environmental deterioration resulting from such misuse. That agency has long uncritically promoted pesticides, often displaying a distressing degree of ignorance of ecology in the process. An outstanding example can be found in the history of the fire-ant program, in which the USDA in the late 1950s attempted to "exterminate" that insect over a large portion of the United States by spraying with the chlorinated hydrocarbons dieldrin and heptachlor. Many independent biologists protested the program, asserting that extermination of the ants would be virtually impossible and that the unwanted side effects would be horrendous. Undaunted, the USDA forged ahead, but by 1960 it was clear that the program was a fiasco, as predicted. The disaster is examined in detail in Appendix 3.

With respect to the fire ant, however, the USDA apparently was incapable of learning. Armed with a new chlorinated-hydrocarbon insecticide, mirex, the department announced plans in 1970 to spray bait pellets over some 4.5 million hectares in the South. During the previous eight years, mirex had already been used over large areas on an experimental basis against the fire ant. It was at first touted as the perfect pesticide for the program, because virtually all the bait found its way into the ants' nests, leaving very little to poison nontarget organisms, and it appeared to be generally less toxic than other chlorinated hydrocarbons such as dieldrin or heptachlor. But, as time and research went on, it was discovered that mirex was not so harmless, after all. Like other chlorinated hydrocarbons, it is persistent and tends to be concentrated in food chains. [72] In laboratory tests, it has been found to be highly toxic to shrimp, crabs, and crayfish, as well as to insects other than the fire ant. It is also somewhat toxic to at least some birds and mammals and is carcinogenic in mice. Because of overtreatment (repeated applications after most of the ant nests had been poisoned), enough mirex escaped into the environment to cause problems.

When the USDA announced the new program, the Environmental Defense Fund, together with several other conservation groups, filed suit against it. In April 1971, their motion for a preliminary injunction against the fire-ant program was denied, and the program was initiated immediately. However, the action had served to delay its start. Moreover, perhaps partly because of the suit and partly because some states failed to produce their shares of the funds for it, the originally planned program was considerably curtailed.

For some insight into the political problems of opposing the pesticide industry, see the account of van den Bosch's efforts to produce a report for the EPA on the benefits and costs of cosmetic pesticide application in Robert Wuliger, "The cosmetics of agribusiness".

[71] Personal communication, June 1, 1976.

[72] P. W. Borthwick; T. W. Duke; A. J. Wilson, Jr.; J. I. Lowe; J. M. Patrick, Jr. ; and J. C. Oberheu, *Accumulation and movement of mirex in selected estuaries of South Carolina*, 1969-71.

A number of other government agencies became interested in mirex. The Department of the Interior put mirex on its list of restricted pesticides, and the Department of Health, Education and

Welfare disapproved of mirex because of its carcinogenic properties. The Council on Environmental Quality also recommended against the use of mirex, and the Environmental Protection Agency (EPA) in 1972 limited mirex applications to once a year and to areas away from forests and waterways (three times a year without spatial restriction had been the practice). In 1975 the USDA at last abandoned the goal of eradicating the fire ant. Secretary of Agriculture Earl L. Butz gave as the reason the EPA restrictions, which he said would turn USDA operations "into a control program of living with the ants rather than working toward an eradication program to wipe them out." [73] In late 1976, the USDA and the EPA settled the six-year-old battle over mirex with an 18-month phaseout program. [73a] But it is likely that the USDA will continue the attack on fire ants with some new compound. Although *no* widespread insect pest has ever been eradicated by pesticides, and none is ever likely to be, this news has yet to penetrate the appropriate recesses of the USDA. In 1974, for instance, the department seriously recommended a scheme to "eradicate" the boll weevil. Whether or not that program will be attempted remains to be seen [74] Whether it would be successful is less in doubt.

Not all pest-control programs initiated by the USDA have been so incompetent. Some ecologically sophisticated programs have been initiated within the department. Perhaps the most brilliant was that against the screwworm, a fly whose larvae (maggots) can be an extremely serious pest on cattle. Annual losses in livestock because of that pest were estimated to have been as much as $40 million a year in the early 1960s. Under the leadership of entomologist E. F. Knipling, the USDA embarked on a massive program of sterilizing male screwworm flies by irradiation and then releasing them in infested areas. The female screwworm only mates once. By flooding infested areas with sterile males, the screwworm was essentially eradicated from the southeastern United States. The effectiveness of that biologicalcontrol program makes an interesting contrast with the futile and destructive fire-ant program.

Alternative Methods of Controlling Populations of Insects and Mites

There are three main reasons why the broadcast use of synthetic poisons is a generally undesirable way of controlling the sizes of pest populations. The first, demonstrated in Chapter 10, is that it exposes human beings to compounds that often have high acute toxicity and to others that may have long-term effects on health, including the induction of cancers. The second is that, by affecting nontarget organisms, synthetic poisons may disrupt the crucial service functions of ecosystems upon which human beings depend. One of those functions is, ironically, the control of some 98 or 99 percent of the potential pests. [75] When that function is disrupted by the use of pesticides, the result, as in the Cañete Valley, is the promotion of organisms that have been released from natural controls to pest status.

The third reason the broadcast use of synthetic poisons is undesirable is that such use encourages the development in pests of resistance to the pesticides. This problem is so serious that it has been described as a "primary obstacle to successful pest control today." [76] Some major insect pests are now resistant to nearly all the insecticides registered by the U.S. government for their control.

These failings mean that not only does broadcast spraying represent both direct and indirect hazards to human beings, but that very often the spraying does not control the pest -- and even

exacerbates pest problems. Nevertheless, we could gain the impression from pesticide industry propaganda that only current patterns of chemical control stand between us and death from insect-borne disease or starvation. Nothing could be further from the truth. There are, in many cases, alternatives to broadcast use of pesticides that are more

effective in controlling pests and that pose little or no threat to people or ecosystems.

Biological control by predators and parasites. Perhaps the best known of those alternatives is biological control using predators and parasites. [77] In essence, this is employing the same technique "used" by natural ecosystems to achieve near-perfect control of potential pests. When a pest problem arises, organisms that attack the pest are introduced, and nature takes its course.

The first (and still most famous) case of biological control is the saga of the cottony-cushion scale. This scale insect, *Icerya purchasi*, a native of Australia, was discovered in California in 1868 and by the mid-1880s was in the process of destroying the California citrus industry. A parasitic fly and a predatory beetle were imported from Australia, where those and other natural enemies kept *Icerya* from becoming a pest. The importations occurred in 1888 and 1889 and achieved spectacular success. By the end of 1889*Icerya* had ceased to be a problem in California. The beetle (the Australian ladybird or vedalia beetle) achieved the first great success, spreading rapidly, but it is clear that the fly would have been equally successful, and today it is the primary control factor in coastal areas. [78]

There is an interesting footnote to that biologicalcontrol success story. In 1945 and 1947 DDT was first widely used on citrus in California. The spraying decimated populations of the vedalia beetle and caused a catastrophic population explosion of the cottony-cushion scale, which had been demoted to a nonpest status for more than half a century. Severe economic damage was done in just a few years until the spray programs were discontinued and biological control reestablished. [79]

There are many other biological-control success stories, but they are little known to the public. At small expense and effort a pest problem can thus be solved once and for all. The continuing, expensive effort -- often with ever-increasing failure of control and harmful side effects -- that characterizes many chemical-control programs, is absent. Only monitoring is required to make sure the biological control continues to work. By importing predators or parasites some degree of permanent control has been achieved on some 130 insect pest species. About one-third of them have been completely controlled, one-third substantially controlled, and one-third partially

controlled. Some of the insects have been the targets of control programs in more than one country -- all told, there have been worldwide some 275 successful biological-control projects. [80]

All in all, there appears to be about a 50-percent chance of achieving significant control of an insect pest by importing natural enemies to attack it. Nevertheless, of some 5000 recorded species of insect pests around the world, attempts have been made to find and import natural enemies of fewer than 5 percent. [81] But, of course, there is no profit for the petrochemical industry if pests are controlled by natural enemies (and relatively little profit even if chemical controls themselves work!).

Another type of biological control with the potential for being as effective as the use of arthropod enemies of insects is the dispersing of bacterial, fungal, and viral parasites that also attack the insects. Although up to 1959 there were only two such microbial insecticides on the market, by 1975 nearly fifty had been given trade names and were in commercial or experimental use. It has been estimated that, for example, the successful use of the pathogen *Baculovirus heliothis* to control pink bollworms on cotton could reduce the use of synthetic pesticides by at least 8 million kilograms annually. [82]

The importation of natural enemies is not without risk, it must be noted. For example, the introduction of mongooses into Jamaica to control rats led to an ecocatastrophe in which the native fauna of birds and small land animals was decimated. Today, however, importing agencies have established extremely careful protocols to screen out such "bad actors," doing careful preimportation experiments in special fail-safe quarantine facilities.

Biological control by genetic methods. Other forms of biological control have also been successful.

The sterile-male technique has already been discussed in connection with the screwworm program in the southeastern United States. That biological-control programs once successful may not be permanently successful is shown by the history of attempts to control screwworms along the border between the United States and Mexico. Conditions there were not as favorable to the technique, and initial successes in the mid-1960s were followed by a resurgence of screwworms in the early 1970s -- a resurgence made more serious because ranches then lacked the skilled cowboys, trained horses, and necessary facilities to reinstitute older methods of control. [83] One of the problems was that in the sustained program necessary to prevent reinfestation by

screwworms from Mexico (in contrast to the "quick fix" in the southeast) maintaining the genetic quality of the stocks used for release required genetic monitoring, which was not done properly.

Unfortunately, it appears that the selection pressures inadvertently applied in the laboratory produced a strain in which the males could not compete with wild males. This led to a collapse of control. [84] The USDA is now attempting to remedy these problems. Among other things, it is contracting for extensive genetic research. [85] The crucial point is that no pest-control program, biological or chemical, can ever really be considered a *permanent* success -- monitoring and backup plans in case of resurgence or reinfestation should always follow any successful program.

The success of the screwworm program has led to intensive investigations of other methods of *genetic control* of pest populations. [86] A great deal of attention has been paid, for instance, to the use of natural sterility produced by chromosomal rearrangements, and other techniques such as inducing sex-ratio distortion have been considered. So far, successes have been limited to pilot studies, [87] but there is every reason to believe that there will be future successes of the kind achieved with the initial screwworm program.

Biological control by cultural and hormonal methods. Another form of biological control is so-called *cultural control*, in which conditions in the crop ecosystem are modified to the detriment of the pests or to the advantage of their natural enemies. Weeds or crop remains that harbor pests can be destroyed, planting or harvesting dates modified, crops rotated, several crops planted together, and so on. Perhaps the most promising form of cultural control has already been discussed in Chapter 4 -- the genetic enhancement of plant defenses to produce strains resistant to pests, to aid crops in their coevolutionary races with the organisms that attack them. Research is also being carried out with a view to isolating and making use of plants' natural chemical defenses against insects and plant diseases. [88a] For instance, one group of chemicals seems to inhibit the juvenile hormones of insects, thus disrupting their development. Another substance appears to elicit in plants a generalized response to diseases.

The use of attractants, especially of pheromones (hormones that operate outside the body -- in this case, sex lures used by insects to attract mates), [88] has had limited but important success in pest control. It has been especially effective against tephritid fruit flies, which often do major damage in orchards and melon fields. An artificial sex pheromone, methyl eugenol, has achieved several local eradications of *Dacus dorsalis*, the oriental fruit fly, and eugenol is used as the lure in traps that are monitored to detect importations of that important pest. FIGURE 11-9 Hormonal activity in the Cecropia moth, the animal used for much of the early experimental work on the control of insect growth and metamorphosis. Juvenile hormone (broken line) comes from the corpora allata, tiny glands just behind the brain. A second substance, brain hormone, stimulates the prothoracic gland to secrete ecdysone, which initiates the shedding of the external skeleton as the caterpillar grows. The caterpillar stage is controlled by a balance of juvenile hormone and ecdysone. In the normal course of development the flow of juvenile hormone is stopped when the caterpillar is full grown, permitting metamorphosis into the pupa (the resting stage in which the adult structure is formed.) If more juvenile hormone is applied after its natural production ends, development is deranged; the hormone then acts as an insecticide. (After Williams, 1967.)

Besides using external hormones to lure insects to their deaths or to disrupt their mating behavior, [90] internal hormones can be used to disrupt their development (which is controlled by a balance of juvenile hormones and those causing metamorphosis, Figure 11-9). Such so-called

third-generation insecticides [91] are now undergoing field testing. How great a problem the evolution of resistance to them will present is still unknown. In theory, insects can evolve behavioral mechanisms to avoid exposure, barriers to prevent absorption, or tolerance to greater variability in hormone levels, but whether such changes will occur in practice is an open question.

Integrated control. There obviously is no single panacea to replace the broadcast spraying of pesticides. What is required is a shift to ecological pest management [92] -- that is, to what is often called *integrated control*. Integrated control has as its goal the maintenance of potential pest populations below the levels at which they cause serious health hazards or economic damage. It does not attempt to exterminate pests -- which, as stated earlier, has never been accomplished by the broadcast spraying of pesticides. Integrated control involves using one or more techniques appropriate to the particular pest situation. Mosquitoes may be controlled by draining swamps in which larvae live, stocking lakes with mosquito-eating fishes, or applying hormonal insecticides, or perhaps directly applying toxic nonpersistent insecticides to any standing water that will not support fishes and cannot be drained. Similarly, a crop could be protected by practices such as planting it in mixed cultures with other crops, destroying pest reservoirs adjacent to fields, introducing and encouraging appropriate predators and parasites, enhancing the natural defenses of crop populations, luring pests from fields with baits, and using nonpersistent insecticides. These and other practices may be combined to achieve both high levels of desirable control and a minimum of damage to the ecosystems of the world. Sometimes, as in

the successful screwworm program, no chemical control will be necessary; at other times chemical methods may play major roles.

Integrated control programs have been enormously successful where they have been tried. An outstanding example is a program in cotton in California. Robert van den Bosch and his co-authors wrote [93] about the control of pests on cotton in California's Central Valley, "Existing pest control practices are both inefficient and expensive, and because of this they are directly contributing to the economic crisis [among cotton growers]. Accumulating evidence indicates that integrated control is much more efficient and less expensive, and the hard-pressed growers are beginning to realize this."

Another successful integrated control program has been established in three California cities (Berkeley, Palo Alto, and San Jose) to protect Street trees. [93a] Since this protection is mainly for cosmetic purposes, the customary heavy use of poisons is even less justifiable than it is on farm produce. Once established, the urban integrated control program appears to be less costly to taxpayers as well as far less of a threat to their health.

The transition away from the relatively simple chemical techniques will require planning and training, and will perhaps produce some temporary economic stress. One county agricultural extension service entomologist, faced with a successful integrated-control program, said, "Your damn pest management program is ruining my business. I can't get pilots who are willing to work for me when there is so little insecticide being used." [94] Such attitudes are, quite naturally, widespread in the insecticide industry, where profits depend on the avoidance of permanent solutions to pest problems -- other than perpetual spraying.

Since banning the chlorinated hydrocarbons should not be delayed, more expensive methods of control may have to be used temporarily. But there is no reason the transition should have serious consequences for human health or nutrition. The step would be necessary, however, even if such consequences *were* foreseen as serious, since continued use of persistent insecticides risks an unprecedented catastrophe for the entire planet. In fact, positive benefits would be immediate in many areas, where the development of DDT-resistant mosquitoes is already reducing the effectiveness of mosquito-control programs. It is important to remember, above all, that avoiding unhappy side effects from any control program, integrated or not, depends on intelligent surveillance and periodic reevaluation. *Any* tinkering with ecosystems may have unforeseen and deleterious consequences.

Herbicides in Ecosystems

In recent years there has been an enormous upsurge in the use of herbicides as a substitute for farm machinery and labor in cultivating crops to increase productivity of range and pastureland; [95] for keeping roadsides, railroad rights-of-way, and powerline cuts free of shrubs; and as military defoliants during the Vietnam war. The rate of increase in herbicide use has far outstripped that of synthetic insecticides, and annual sales of herbicides are now larger. [96] Several kinds of herbicides are in wide use (Box 11-2). Members of one group (2,4-D; 2,4,5-T; picloram; and so on) are similar to plant hormones and cause metabolic changes in the plant that lead to death or leaf drop. Members of another group (simazin, monuron, and the like) interfere with a critical process in photosynthesis, causing the plant to die from lack of energy. The way others disrupt plant metabolism is less well understood. Although their direct toxicity to animals is low, herbicides have great impact on animal populations, since all animals depend on plants for food, at least indirectly. Furthermore, as a result of the coevolutionary interactions discussed earlier, most herbivorous animals are specialized to feed on one kind or on just a few kinds of plants.

BOX 11-2 Some Synthetic Herbicides

Herbicides That Mimic Indoleacetic Acid

This group of herbicides includes 2,4-D, 2,4,5T, picloram, and several others. The compounds are chemically similar to the growth-regulating substance indoleacetic acid. That plant hormone (an auxin) controls such diverse activities as shoot growth, root growth, apical dominance, and phototropism. Herbicides in this hormonelike group function by causing uncontrolled growth and metabolism -- the plant, in essence, grows itself to death. *

Indoleacetic acid does not function as a growth substance in animals, and therefore it is not surprising that these herbicides have essentially no direct effect on animals. Differential toxicity to broad-leaved plants (in contrast to narrow-leaved grasses) is a function of the greater ease with which the compounds are absorbed by the broad-leaved plants. Some of the herbicides, such as 2,4-D, are rapidly metabolized in woody plants, which usually localize the damage (they are defoliated but not killed). Other herbicides, such as picloram, remain active for long periods in trees and ecosystems.

Symmetrical Triazines and Substituted Ureas

These two classes of compounds include atrazine, simazine, fenuron, diuron, and monuron. Both kinds of compound block a critical step in photosynthesis, known as the Hill reaction. The plant, in essence, starves to death. Since animals do not photosynthesize, they are not directly affected by these compounds, with the exception of possible mutagenic effects from the triazines.

Others

A wide variety of other synthetic compounds, including chlorinated aliphatic acids (dalapon, TCA), phenols (DNBP), acetamides (propanil) and thiocarbamates, can act as herbicides. Their modes of action are varied, and many are poorly understood. For instance, the carbamate sulfoxides interfere with plant metabolism and growth and are often highly selective, but the precise mechanism for their action has not been discovered. They are, however, highly biodegradable -- and the mechanism of their metabolic destruction is fairly clear. **

In the light of these considerations, it is possible to evaluate the statements made by many United States government officials concerning the lack of danger to animals or the uncertainty of effects on animals of our defoliation activities in Vietnam (Box 11-3). Defoliation of tropical jungles inevitably leads to the local extinction of many populations of insects, birds, arboreal reptiles, and arboreal mammals. But, of course, *animals* in official statements can all too often be translated "elephants, tigers, and other large mammals." In temperate forests there is generally a less distinct canopy fauna, but changes in animal populations in response to large-scale defoliation would certainly be tremendous.

Little is known about the direct effects of herbicides on soil microorganisms. Research in Sweden indicates that herbicides destroy bacteria that are symbiotic with legumes, although the bacteria apparently are capable of developing some resistance. [97] Some herbicides, such as 2,4-D, are quickly degraded by bacteria and persist for only a few weeks or months; others (2,4,5-T and, presumably, picloram) are more persistent. Soil microorganisms (primarily bacteria and fungi) do not photosynthesize; they are consumers, not producers. Therefore, they probably will not be affected by herbicides that block photosynthetic processes, although there could, of course, be other metabolic effects. Herbicides that function as simulated plant hormones are unlikely to disturb the growth processes of the soil flora, since there is no evidence that the plant hormone simulated by those substances functions in bacteria or fungi. Those herbicides may, of course, have other physiological effects, since, as noted, some are metabolized by soil bacteria.

BOX 11-3 Ecocide in Indochina

The practice of genocide, unhappily, has a long history in human affairs. Ecocide (the deliberate destruction of ecosystems) is for practical reasons a rather recent development. Destruction of enemy crops has frequently occurred in warfare, and the near-extermination of the bison was a decisive factor in America's conquest of the Plains Indians (the slaughter was not a purposeful military strategy, but its effects were known at the time). But, until recently, humanity has not been able to destroy the entire life-support system over substantial portions of the surface of Earth in a short space of time. Now, however, synthetic herbicides, insecticides, weathermodification technology, and nuclear weapons have given people a greatly increased capability of committing ecocide. If the widespread use of biocides continues, despite growing knowledge of the probable consequences, civilization may destroy much of the carrying capacity of this planet for human life. If that occurs, however, survivors will be able to explain what happened as a result of greed and stupidity -- after all, no one really wanted the unhappy side effects of synthetic biocides.

But no such excuse can be made for the practice of ecocide by the armed forces of the United States in the Vietnam war. [a] In that war the United States attempted to win by substituting firepower for manpower. It managed to retain control of the main cities, so the vast majority of its firepower was concentrated on the countryside, rather than on population centers. The people in rural areas and agricultural and natural ecosystems bore the brunt of the assault both with "conventional" weapons and with herbicides and other technologies for ecosystem alteration and destruction.

According to a report of the National Academy of Science (NAS), through 1971 -- when spraying stopped -- some 1.5 million hectares of South Vietnam, 10 percent of the country had been treated with about 20 million gallons of herbicides, [b] applied at an average of 13 times the dose recommended by the U.S. Department of Agriculture for domestic use. Most of the spraying was done in forests in an unsuccessful attempt to expose the enemy and secure the area (as indicated in Table 11-2). At such dosages some of the trees, especially mangroves, can be not just defoliated but killed by a single application (see Figure 11-10). Multiple applications kill other kinds of trees. The American Association for the Advancement of Science HerbicideAssessment Commission (AAAS-HAC) reported that perhaps half the trees in the mature hardwood forests north of Saigon were damaged. One of the herbicides widely used in Vietnam was picloram, which is both potent and (like DDT) persistent. It is so dangerous that the Department of Agriculture has not licensed it for use in the cultivation of any American crop.

By the end of 1971 at least 100,000 hectares of cropland in South Vietnam had been sprayed with herbicides (Table 11-2) with the stated purpose of denying food to enemy soldiers. This was done in an attempt also to starve civilian populations sympathetic to the National Liberation Front and to force people to move from the countryside into cities, where they would be easier to control. As our military was well aware, the first to suffer when food becomes scarce in wartime are not soldiers, but children, old people, and pregnant and nursing women. The AAAS-HAC reported that virtually all the crops destroyed would have supplied food to civilians, especially to the Montagnard tribesmen of the central highlands.

The general effect of the herbicide programs was to degrade Vietnamese ecosystems. Forests attacked with herbicides have been invaded by bamboo, and some areas may have undergone laterization. The danger of laterization is especially severe in farmland attacked with herbicides. Large areas of mangrove forest, which grows along waterways and plays a critical role in the maintenance of economically important fisheries, have also been destroyed. According to the NAS report, about 36 percent of the mangroves in South Vietnam (0.6 percent of the country's area) have been killed, and the forests will not recover for perhaps a century. [c] The long-term consequences of the programs are incalculable, since they have also certainly had a profound effect on the fauna of the area (and animals, in turn, are important to the plants for pollination and seed dispersal) and probably also on the organisms of the soil, which are essential to its fertility. Very often in Vietnam plant succession in repeatedly defoliated areas has resulted in the establishment of an impoverished community dominated by bamboo or low grasses of no use to the Vietnamese.

[c]Ibid.

BOX 11-3 (Continued)

Herbiciding operations also may have left the Vietnamese with a legacy of birth defects, as some of the constituents of herbicides are teratogenic. [d] Due in large part to the AAAS-HAC report and other pressures from the American scientific community, the use of herbicides as a military weapon in Vietnam was discontinued in May of 1971.

Herbicides were not the only ecocidal weapon used in Indochina. In 1967/ 1968 alone, more than 3.5 million 500-to-750-lb (225-340 kg) bombs were dropped on Vietnam, each creating a crater as much as 14 meters across and 9 meters deep. If those craters were placed in a line, they would stretch for some 50,000 kilometers, a distance longer than the circumference of Earth. They occupy 40,000 hectares.

From 1965 to 1973 the U.S. military detonated 7 million metric tons of high explosives in South Vietnam, the equivalent to the explosive power of 400 Hiroshima-size atomic bombs-almost half a ton of munitions for each hectare of South Vietnam's land area. The area of craters created in South Vietnam by bombs and shells was some 150,000 hectares (almost I percent of the land), 2 billion cubic meters of soil were displaced, and millions of additional hectares were contaminated with missile fragments. [e] In many areas of Vietnam, peasants are afraid to reoccupy bombed fields because of the danger from unexploded ordnance.

FIGURE 11-10 These aerial photos show the extent of damage to South Vietnamese mangrove forests from U.S. military herbicide spraying. *Top.* An unsprayed mangrove forest about 60 miles from Saigon. Center. In 1970, a oncesimilar forest five years after spraying. Dark spots are surviving trees. *Bottom.* A herbicide-damaged rubber plantation about 40 miles north of Saigon. The dead trees in the foreground have been cut down. In the background, among other dead rubber trees is a plantation workers' resettlement. (Wide World Photos.)

Many of the bomb craters pocking the surface of Indochina are permanently filled with water. From our observations of World War II bomb craters in New Guinea and the Solomon Islands in 1965, we believe it is reasonable to expect natural recovery of many such cratered areas to take at least a century.

Another ecocidal device that was used by the U.S. in Indochina was the BLU-82B multipurpose bomb, the so-called daisy-cutter. That 15,000-pound (6800-kg) concussion weapon cleared an area the size of a football field to make an "instant landing zone" for helicopters. It was also used as an antipersonnel weapon, as it could kill all plant and animal life within a radius of some 65 meters (an area of more than 1.3 hectares), and the zone of death and injury extended some 400 meters (an area of 50 hectares). Hundreds of those devices were used in Vietnam. [f] Also used for clearing landing areas as well as against troops was the CBU-55 fire air explosive. It produces an exceedingly powerful blast by spraying an aerosol cloud of fuel over the target area and then detonating it. Blast overpressures of about 20 kilograms per square centimeter are produced over a circle of 15 meters in diameter. [g] The bomb was introduced into the Vietnam war in 1971 by U.S. forces and was used after their departure by South Vietnam. According to the United States Department of Defense, 2000 of them were dropped by the South Vietnamese air force between 1972 and 1975. They were also used by Cambodian government forces in Cambodia. Information on the scale and permanence of the damage done in either country is not available.

Perhaps the crudest tool the United States used to destroy the ecology of Indochina was the Rome plow. This is a heavily armored D7E caterpillar bulldozer weighing 33 tons and carrying a

blade designed to cut down a tree of any size. Rome plows were first used in 1966 to clear several hundred yards on both sides of all main roads in South Vietnam. In 1968 they were distributed to "land-clearing companies," each with thirty plows, to mow down any Vietnamese forests thought advantageous to the enemy. Each company had the capability of clearing 40 hectares per day of fully developed upland forest or 160 hectares per day of light jungle. About 350,000 hectares of South Vietnamese forest (3 percent of South Vietnam's forests, 2 percent of its land area) were plowed as were thousands of hectares of rubber plantations, orchards and farms. [h] The immediate ecological damage caused by exposing and abrading the soil surface over such huge areas is colossal, and the subsequent establishment of undesirable plant communities all too common.

Ecocide in Indochina was not limited to combat operations. A clandestine raid in April 1969 defoliated 70,000 hectares in eastern Cambodia and damaged about a third of the rubber trees then in production in Cambodia. The damage was concentrated in an area with the highest yield per acre in Cambodia. In addition to that serious blow to the rubber crop (which is the underpinning of that nation's economy), damage to local food production was severe. The operation was carried out before the Cambodian

invasion in order to put pressure on the Sihanouk government, and the raid may have been flown by persons employed by the U.S. Central Intelligence Agency. [i]

Although ecocide is not formally a war crime, it contributed much "wanton destruction" and "devastation," which are considered both war crimes and crimes against humanity under the charter of the International Military Tribunal at Nuremberg. The use of herbicides (and tear gases) is against the Geneva Protocol of 1925, as interpreted in 1969 by the main political committee of the U.N. General Assembly. The vote on that was 58 to 3, with 35 abstentions. The only nations to vote no with the United States were Australia, which allied itself with the United States in Vietnam, and Portugal, which employed those weapons in its own wars in Africa. [j]

The effects of herbicides on soil are not necessarily all negative, however. The principal reason for plowing is to destroy weeds, and the process of removing crop debris, leaving fields bare, and then plowing them is a major source of soil erosion. Erosion is an extremely serious problem -- as much as one-third of the topsoil in parts of the United States has been lost to it in the past century. [97a] With the massive use of herbicides, a "zero-tillage" system can be established, in which herbicides substitute for plowing and the land is subject to far less erosion. Such a system has been in use in the southeastern United States on 1 million hectares for several years. [98] Whether that benefit of the massive use of herbicides outweighs the costs remains to be seen; we

are doubtful -- especially in view of their possible direct effects on people, discussed in Chapter 10. Some combination of minimum tillage with other methods of weed control may prove superior from the ecological / soil-conservation point of view.

Herbicides have also been adopted by other organisms than human beings. A flightless grasshopper has been discovered to secrete 2,5-dichlorophenol, apparently derived from 2,4-D, along with other naturally occurring disagreeable substances derived from plants, in its defensive fluid. This unusual ingredient appears to be very successful in discouraging predatory ants; thus, in attacking weeds, human beings inadvertently encourage a herbivore. [99] The subtlety of the effects of biocides is difficult to overestimate. For example, herbicides can serve as synergists of insecticides, and the nature of the synergism is itself influenced by such other environmental factors as soil type. [100]

Too little is known also about the effects of herbicides on aquatic life, but the evidence is mounting that they are substantial. Members of the group including 2,4-D are particularly toxic to fishes, although less so than most insecticides, and they have also been found toxic to freshwater crustacea. [101]

The runoff of herbicides, especially those that interfere with photosynthesis, into inland and coastal waters could be more serious than the effects of herbicides on soil fertility. The photosynthetic processes of phytoplankton, as well as the growth of other plants, could be disturbed. Again, it is important to remember that changes in basic producer populations will inevitably affect populations higher up in the food chains. The need for comprehensive studies of the effects of herbicides in aquatic ecosystems is escalating as those chemicals not

only enter aquatic systems as runoff but are applied directly for aquatic weed-control. [102]

Even with the small amount of information that exists, it is hard to be complacent about widespread indiscriminate use of herbicides under any circumstances. The spraying of potent biocides over large areas because it is easier and quicker than careful cultivating or weeding is a practice ecologists can only deplore. The herbicide story may turn out to be a repetition of the insecticide story, but the case for dependence on chemicals seems even weaker for weed-killers. Like insecticides, they should be used with discretion and only when necessary. Otherwise, problems such as development of resistance in weeds may be added to the growing concern over direct effects (Chapter 10) and the effects of these compounds on the ecosystem. Some weeds have developed resistance to herbicides, as have some crops. [103] The latter may be an important advantage if crop strains can be developed that will permit the action of herbicides to be more selective.

More attention should be paid to developing integratedcontrol methods for weeds, and in recalcitrant cases where those methods or mechanical weeding proves infeasible, a return to weeding by human effort should be considered. Adjustment of the economic system so that more labor can be employed profitably in agriculture might possibly help solve social and economic problems ranging from unemployment to overurbanization.

Quantitative Pollutants with Known Ecosystemic Effects

Most attention to the impacts of pollutants on natural ecological systems has been directed at pesticides. And, with the exception of radiological pollutants (see below), detailed studies of the effects of a given pollutant on an entire terrestrial ecosystem have been confined very largely to synthetic insecticides. [104] It is clear that many other qualitative pollutants (such as the PCBs) must have ecosystemic effects but they have at most been guessed at.

We now turn to a consideration of some of the quantitative pollutants -- petroleum, mercury, nitrates, phosphates, and radiation. Ecological systems have had to deal with all of them for eons, but now they may be present in quantities that constitute overloads for the systems in which they occur.

Petroleum pollution. One ocean pollutant that has received a great deal of publicity -- much of it the result of spectacular supertanker accidents -- is oil. In 1970, when Thor Heyerdahl sailed a papyrus raft across the Atlantic Ocean, he reported, "Clots of oil are polluting the mid-stream current of the Atlantic Ocean, from horizon to horizon." [105] Oil has reached the sea in a variety of ways. Among them are the massive accidental spills from tankers that have received so much publicity, as well as many smaller spills. Those probably account for less than 0.1 percent of the total amount of oil transported at sea. But the volume is so huge (about 1.2 billion metric tons per year, or 60 percent of all sea-transported goods) that the spills and oil purposely flushed from tankers amount to a considerable influx. [105a] Another source is fuel oil spilled from ships not involved in transporting oil, especially in connection with their refueling operations. In addition to shipping spills, there have been accidents in the extraction of oil from the seafloor, of which the 1969 Santa Barbara leak is the most widely known example. Some oil reaches the sea in sewage as wastes from automobile crankcases and from industry (including refineries). There is also the natural influx of oil into the oceans from submarine seeps. Those may be important

locally, but on a global scale the input from seeps appears to be about 10 times smaller than human contributions. [106] Estimates of the magnitudes of major

[102] For insight into some of the complexities of herbicide effects, see R. L. Simpson and D. Pimentel, *Ecological effects of the aquatic herbicide fenac on small ponds*.

sources of petroleum in the oceans are given in Table 11-3.

The effects of oil pollution on oceanic ecosystems, beyond the immediate and obvious decimation of populations of fishes, shellfishes, and seabirds at the site of a spill (Figure 11-11), are now being discovered, thanks in part to a relatively small spill that occurred in 1969 near the

Woods Hole Oceanographic Institute in Massachusetts. Effects vary with the type of oil, how far from shore it is spilled, and how long it can "weather" (be degraded by microorganisms, dissolve, and evaporate) before reaching shore, and what organisms live in the affected areas. Some components of oil are toxic; others are known carcinogens. Weathering can reduce their toxicity, but the carcinogenic components are long-lasting. Oil washed to shore lingers on rocks and sand for months or years, but the marine life may need a decade or more to recover, even after the oil is no longer obvious. [107]

Populations of some seabirds, especially the diving birds (such as ducks and puffins in the English Channel), which are most susceptible, have been drastically reduced in recent years, probably largely because of oil contamination. [108] Besides killing thousands of birds directly, oil toxins have been shown experimentally to affect their reproduction and to reduce the viability of their eggs when applied directly to them. Other effects are more subtle but nonetheless cause for concern -- such as the altering of feeding behavior in lobsters. [109]

Detergents used to clean up oil spills have been found to make the situation worse in many cases. [110] Not only are the detergents themselves toxic to many forms of life but they disperse the oil and spread it into new areas. They may also render it more easily absorbable by small marine organisms by breaking it up into droplets.

Immediately after the Massachusetts spill, there was a 95-percent mortality of fish, shellfish, worms, and other sea animals in the immediate area. Nine months later, repopulation had still not taken place. Surviving mussels failed to reproduce. Some constituents of the oil were still present and killing bottom-dwelling organisms eight months later. Surviving shellfish and oysters took in enough oil to be inedible and retained it even months after having been transplanted at a distance. According to marine biologist Max Blumer, there is a possibility that the carcinogenic constituents of oil, which are absorbed unchanged by those and other small organisms, may in time be incorporated into and contaminate entire food chains. [111] Although large amounts would probably spoil the taste and smell of conventional foods, toxic and carcinogenic effects are certainly possible at levels of contamination too low to taste or smell. It has also been suggested that higher levels of contamination might go undetected in fish-protein concentrates, [112] which some people consider to be a potential future source of protein for human beings. To the extent, however, that the carcinogens in oil would accumulate mostly in the fat of fishes rather than in muscle, the carcinogenicity problem in fish-protein concentrates would be minimized.

Some effort is being made to develop bacterial strains that can quickly degrade spilled oil; more efficient technical means of collecting it before it reaches shore are also being developed. [113] In view of the amount of oil

---

[107] There has been some controversy over the effects of oil spills on ecosystems, especially because of differing results obtained by groups studying the 1969 Santa Barbara spill and the Woods Hole group. This controversy is dealt with in D. F. Boesch, C. H. Hershner, and J. H. Milgram , *Oil spills and the marine environment*. The bibliography of this report to the Ford Foundation Energy Policy Project gives entry to the significant literature on ecosystemic effects of oil spills. already polluting the oceans and the increasing potential for further spills represented by the rising volume of oil being transported by sea and the increasing size of tankers, efforts to deal with such accidents should be vigorously pursued. At the same time, much can be done in the area of prevention without further research. Oil can and should be removed from sewage; safety regulations for both drilling platforms and tankers can be tightened and enforced; the flushing of tankers can be prohibited; and other ships can be forbidden to waste or discard oil products of any kind. Legislation covering some of these points has been enacted in the United States, but, with the exception of tracing one tanker responsible for a spill and prosecuting its captain, [114] enforcement before the end of 1976 was virtually nil. [114a]

Mercury and other heavy metals. Mercury, in organic forms such as methyl mercury, has been found experimentally to reduce photosynthesis in marine and freshwater phytoplankton. Photosynthesis was significantly inhibited at concentrations in water of 0.1 parts per billion (one-fiftieth the amount now tolerated by U.S. public-health standards -- 5 ppb). When concentrations of mercury reached 50 parts per billion, growth stopped almost completely. [115] Mercury's effects on phytoplankton resemble those of DDT; like the chlorinated hydrocarbons, it also tends to be concentrated in food chains. [116] Thus, its *potential* impact on oceanic food webs may be serious and similar to that of DDT. The key question in both is whether environmental concentrations of these chemicals, singly or in combination, will ever be high enough to have a significant effect. Like DDT, enough inorganic mercury has already accumulated on lake- and streambeds in North America to provide a serious threat (if the mercury is converted to the soluble organic form) [117] to freshwater and estuarine life for decades to come, unless a way is found to remove it. San Francisco Bay, alone, was estimated by the U.S. Geological Survey in 1971 to have some 52 metric tons of mercury on its bottom, with concentrations ranging from 0.25 to 6.4 parts per *million* in bottom sediment.

What effect mercury has high in oceanic food chains is not clear, however. High levels of mercury in oceanic fishes such as tuna and swordfish may well arise through food-chain amplification of natural oceanic mercury levels, independent of pollution contributions, [118] but that does not necessarily mean that ecological effects from anthropogenic increments of mercury will be absent. It is certainly possible that mercury could have deleterious effects on terrestrial food chains. It has been shown, for instance, that mercuric chloride can be responsible for eggshell-thinning in birds; [119] but high concentrations would appear to be necessary to elicit that effect, [120] and it has been demonstrated *only* for mercuric chloride, not methyl mercury, which is the predominant form in the environment.

There is evidence that mercury may influence community structure by affecting plants and insects as well as higher vertebrates. Laboratory experiments have been done using tomatoes, corn, and beans grown in hydroponic solution with aphids feeding on the plants and lacewings feeding on the aphids. Concentrations as low as 0.006 parts per million (ppm) of methyl mercury hydroxide in the hydroponic solution led to reductions in biomass of the tomatoes, while corn

and beans were about a half and a tenth as sensitive respectively. The aphids concentrated mercury to a level about 1700 times the concentration in treatment solutions and suffered a

[114] *New York Times*, November 8, 1975. The ship was identified by "fingerprinting" the oil -- carefully checking its chemical composition, which is unique for each shipload.

[114a] December 1976 saw a rash of tanker accidents, which cost 9 lives, 50 injuries, and spilled nearly 30 million liters of oil. All five ships involved were chartered in Liberia, and ownership was difficult to determine. One result was renewed discussion of how such accidents could be prevented and safety regulations imposed on foreign-registered ships. Some international mechanism of control is clearly required. (See "Ducking liability at sea", *Environment*, vol. 19, no. 1, January/February 1977, pp. 25ff.)

[115] R. C. Harriss, D. B. White, and R. B. McFarlane, *Mercury compounds reduce photosynthesis by plankton*.

[116] For example, N. Fimreite, W. Holsworth, J. Keith, P. Pearce, and I. Gruchy , *Mercury in fish and fish-eating birds near sites of industrial contamination in Canada*; K. Henriksson, E. Karppanen, and M. Hel minen , *High residue of mercury in Finnish white-tailed eagles*; A. Haney and R. Lipsey, *Accumulation and effects of methyl mercury hydroxide in a terrestrial food chain under laboratory conditions*.

[118] See Barber, Vijayakumar, and Cross, "Mercury concentrations; and the comments on it", *Science*, vol. 178, p. 133 (April 13, 1973). There has also been controversy over whether concentration in fishes increases with age, for example, G. West, "Methylmercury as percentage of total mercury in flesh and viscera of salmon and sea trout of various ages", *Science*, vol. 181, pp. 567-568 (August 10, 1973).

[119] G. Stoewsand et al., "Eggshell thinning in Japanese quail fed mercuric chloride", *Science*, vol. 173, pp. 1030-1031 (September 10, 1971).

[120] Cooke, *Shell-thinning*.

significant decrease in fecundity and lengthened development time when the concentration in the treatment solution was 0.02 ppm. The lacewings concentrated mercury to 4200 times that in the hydroponic solution. [121]

The long-term ecological effects in terrestrial food chains and in the seas of other heavy metals (those with density 5 times that of water or more), such as lead, cadmium, chromium, nickel, and thallium, are not known. But, since they are known to be toxic to many forms of life, [122] it would be unreasonable to assume their effects to be negligible. Some, for example, can be potent inhibitors of photosynthesis. [123]

Air pollution and ecosystems. Air pollution assaults humanity indirectly, as well as directly. The ecological systems of Earth clearly are degraded by the quantitative and qualitative pollutants that are injected into the atmosphere, although we are just beginning to understand some of their effects in detail. Many others are unknown or, at best, guessed at. [124]

In some cases damage is dramatically obvious. For instance, in northern Ontario, Canada, sulfur dioxide pollution has virtually destroyed the natural forest ecosystem for 8 kilometers downwind of an iron-sintering plant and has severely damaged it 16 kilometers or more away. Damage can be detected from the air 30 kilometers from the site (Figure 11-12). [125]

Other damage, less obvious but more important because of the area involved, is done by acid rains falling over a large portion of Europe and the northeastern United States. Sulfur oxides and nitrogen oxides are, as described earlier, injected into the atmosphere in large quantities by the burning of fossil fuels. Those oxides change in chemical reactions in the atmosphere into strong acids--sulfuric and nitric, respectively. Unless

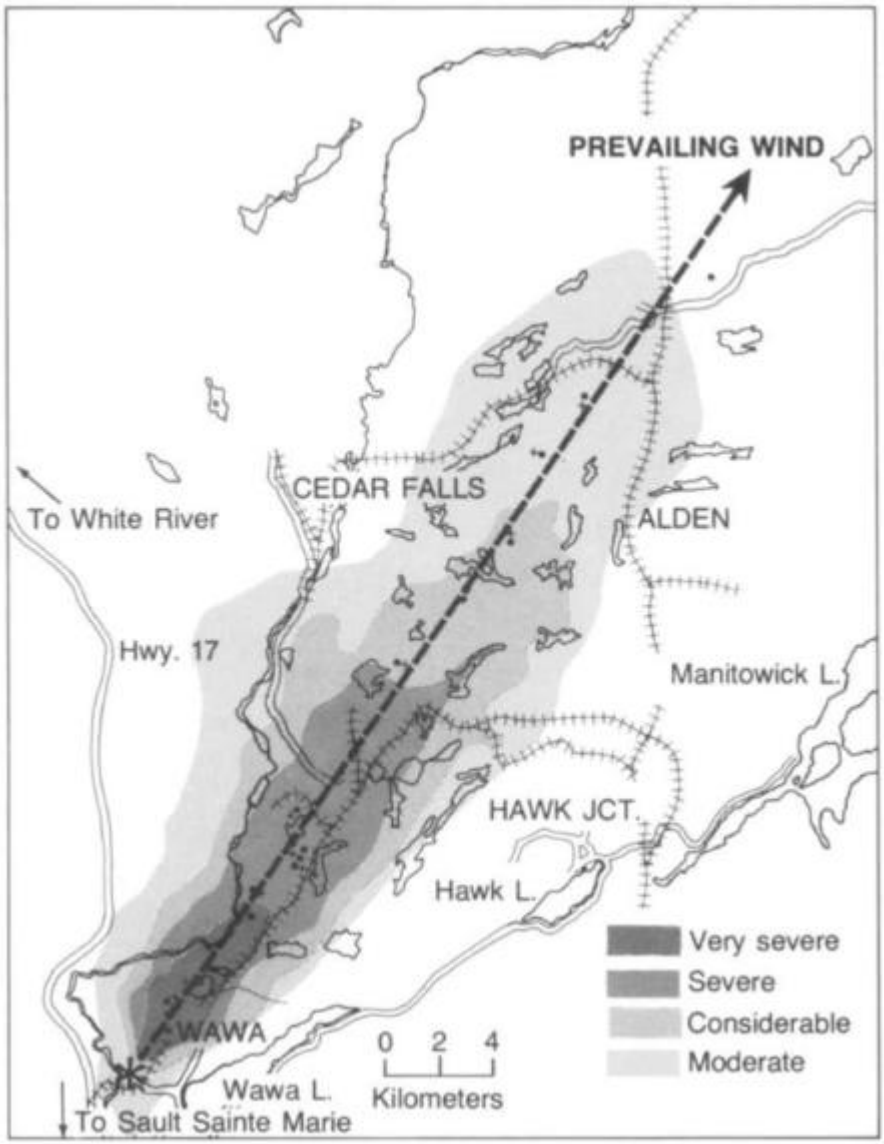

FIGURE 11-12 The extent of damage caused by Wawa, Ontario, iron-sintering plant. Darkest area, very severe; ground vegetation nearly all gone. Next area, severe; all trees gone, most shrubs gone. Next area, considerable; most trees killed. Next area, moderate; trees damaged but little damage to ground flora. (Data from Gordon and Gorham, 1963.)

they are neutralized in reactions with alkaline compounds in the atmosphere, those acids eventually return to Earth in rain. Rainfall in unpolluted areas is normally slightly acid (pH usually is between 5.5 and 6.5) because water and carbon dioxide combine in the atmosphere to form carbonic acid, a weak acid. In the 1970s, the pH of rain over much of the northeastern United States was less than 4, values from 3 to 3.5 were not unusual, and one rain with a measured pH of 2.1 was recorded. [126] (Recall that a drop of 1 pH unit represents a tenfold increase in acidity.) Values of rain pH below 4 have been recorded over much of northern Europe, where the location and

[126] Much of the information in this section is from National Academy of Sciences, *Air quality and stationary source emissions control*, chapter 5 and chapter 7; see also A. Holt-Jensen, *Acid rains in Scandinavia*; G. E. Likens and F. H. Bormann, *Acid rain: A serious regional environmental problem*; N. Malmer, *Acid precipitation: Chemical changes in the soil*.

FIGURE 11-13 The map charts the acidity of rainfall in the United States in the two-week period from March 15 to March 31, 1973. Measurements were made by schoolchildren with a technique accurate to ±0.2 pH and tabulated by the National Oceanic and Atmospheric Administration. The results show significant acidification of all rain falling east of the Mississippi River. (From Stong, 1974.)

spread of the regions affected are well correlated with major sources of sulfur emissions, the growth of those sources, and established patterns of atmospheric dispersion. The pH of rain falling on the United States in two weeks in March 1973, as measured in an experiment involving schoolchildren across the country using a technique with an accuracy of pH ±0.2, appears in Figure 11-13. [127] The spread of acid rain in Europe from 1956 to 1966 is represented in Figure 11-14.

The overall effects of acid rains on ecosystems are not well understood, but they have the potential for serious damage. The rains may modify rates at which nutrients are leached from soils and foliage; they can reduce or exterminate fish populations by acidifying streams; they can affect soil microorganisms, especially those responsible for nitrogen fixation; they can influence the behavior of bacterial and fungal pathogens; they can enhance uptake of the toxic heavy metal cadmium from the soil; and they may interact synergistically with herbicides and other synthetic compounds.

Acid rains were one of the first environmental phenomena to attract attention because of their international implications. Sweden made them the topic of a case study for a United Nations Conference on the Human Environment in Stockholm in 1972. Sweden's forests have suffered a reduction in growth rates starting in the 1950s, thought to be due to acid rains, and salmon and trout have disappeared from Swedish streams and lakes where the pH has fallen much below 5.

[128] The sulfur that rains down on Sweden apparently originates in northwest Europe, especially in the United Kingdom. (Besides the potentially serious ecosystemic effects, Sweden was concerned about the corrosion of structural materials by the

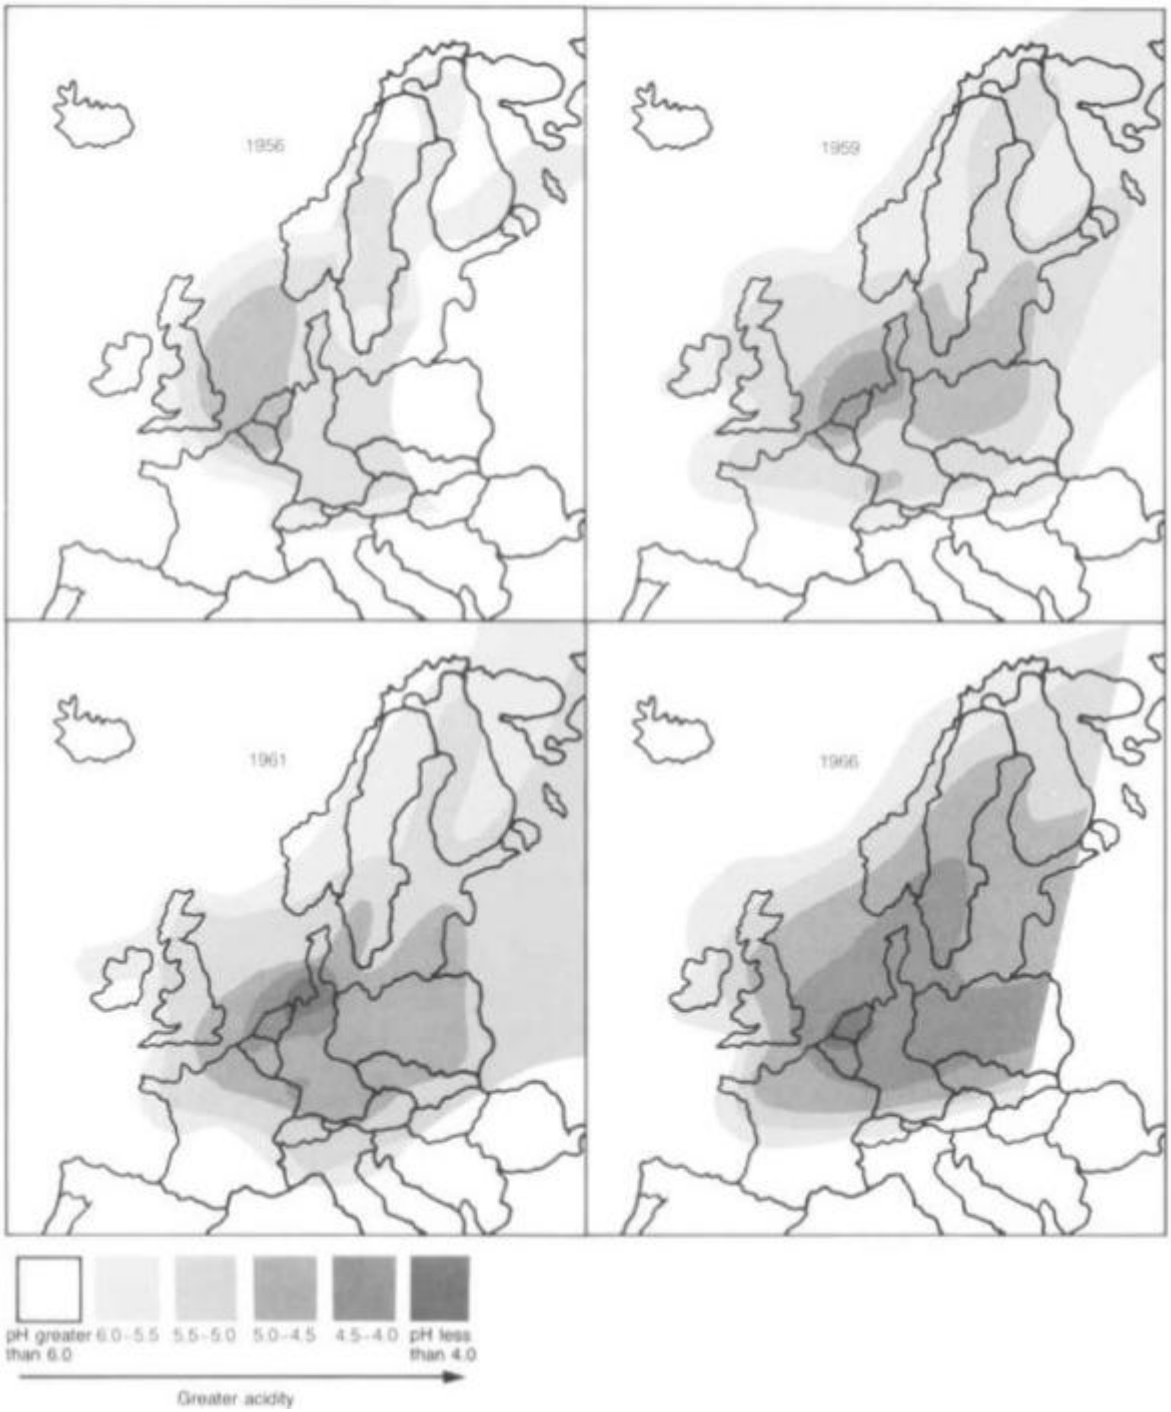

FIGURE 11-14 The steady spread of acid rain in northern Europe from 1956 to 1966 is shown in this sequence of maps. The region of greatest acidity, around Belgium and the Netherlands, reflects both heavy emissions of oxides of sulfur and nitrogen and prevalent meteorological conditions in the region. (From S. Nederbordens Oden *forsurning-ett generellt hot mot ekosystemen. In I. Mysterud, ed., Forurensning og biologisk milijovern, Univeritetsforlaget, Oslo, 1971, pp. 63-98.)*

rains--especially damage to limestone buildings. In Sweden alone the economic value of the damage amounted to $500,000 annually.)

Air pollution can have direct deleterious effects on ecosystems, in addition to causing acid rains. Ozone, which plays such a crucial and positive ecological role in the stratosphere, is extremely damaging to plants. It enters leaves through the pores (stomata) used for normal gas exchange and is thought to alter the permeability of the membranes of cells there. This causes nutrient and electrolyte imbalances and the cells die. Chronic exposure to ozone may weaken plants and make them more susceptible to disease, or it may age them prematurely (cutting yields in crops like citrus)--all without outward signs of injury. Sensitivity in plants is such that a year or two of exposure to relatively low concentrations [15 parts per hundred million (pphm) can significantly alter the composition of a community--with results that could be deleterious]. [129]

Ozone is an important component of photochemical smog (Chapter 10), which contains other oxidants damaging to plants--peroxyacetyl nitrate (PAN) and nitrogen dioxide. PAN is very phytotoxic, more so than ozone, but ozone normally occurs in much greater concentrations. [130]

Photochemical smog originating in Los Angeles (with ozone concentrations of as much as 70 pphm) has had a dramatic impact on the ecosystems of southern California. Some 125 kilometers east of the city two-thirds of the 65,000-hectare San Bernardino National Forest has been affected, and within the affected area 50 percent of the trees have been moderately or severely damaged. [131] In the northeastern United States there is also extensive forest damage from photochemical smog, and concern over ozone damage is growing in the United Kingdom. [132] In those areas the ozone concentration is only one-third or less that of the Los Angeles basin, but ozone is more damaging to the plants in those more humid areas.

The effects of air pollutants on plants can be both complex and subtle. Sulfur dioxide damages plants directly (and differentially) in addition to contributing to acid rain. [133] In the United Kingdom in the summer, however, there is a problem with sulfur-deficiency on nitrate-rich fertilized farmland. The sulfur-dioxide pollution helps to overcome that deficiency, thus stimulating plant growth. There is evidence, however, that this benefit is more than balanced by deleterious effects of the sulfur dioxide on winter growth. [134] Much investigation needs to be done to elucidate such interactions and to determine what effects pollutants have on mutation rates and on the production and germination of seeds. It is also important to identify the ultimate impact of air pollution not just on the plants but on all components of an ecosystem. For instance, fluoride is directly injurious to plants and is also concentrated by them. [135] Under conditions of severe pollution, forage can be so contaminated as to produce fatal fluorosis in cattle, [136] but the effect of lower levels of fluoride pollution on herbivores is unknown. It seems likely that such fluoride pollution would have local ecosystemic effects at most. [137]

Nitrogen, phosphorus, and eutrophication. Nitrogen and phosphorus are nutrients required in large quantities for the growth of terrestrial and aquatic plants. (The natural cycles of both elements and the magnitudes of some of the perturbations imposed by civilization on those cycles are described in Chapter 3.) The heavy use of nitrogen and phosphorus fertilizers has arisen because the availability of the two elements to plants is often the factor that determines how much plant material can be grown. That is, if sunlight, water, and carbon dioxide are

available in abundance, adding nitrogen or phosphorus (whichever is limiting in the given situation), or both, can

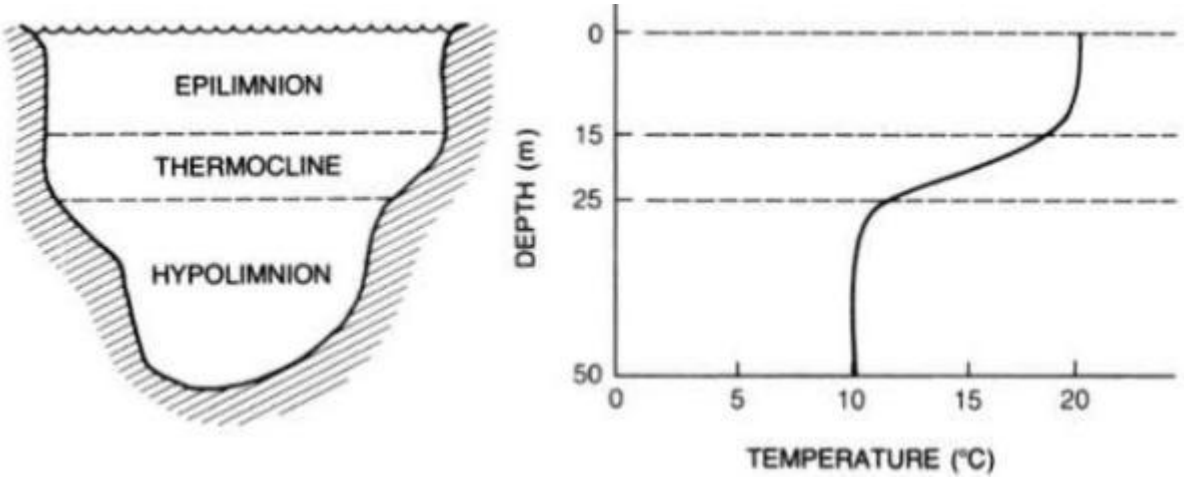

FIGURE 11-15 Thermal stratification in a temperature-zone lake in summer.

increase the yield. (Of course, there are circumstances in which other nutrients--for example, calcium or iron--are limiting.) This situation becomes a liability when extra phosphorus and nitrogen are made available inadvertently to ecosystems in which extra plant growth is undesirable.

The most important example of that phenomenon is in aquatic ecosystems--rivers, lakes, and coastal waters. There, overfertilization can produce overgrowth of aquatic weeds that interfere with recreational uses of the affected bodies of water. More seriously, overfertilization can lead to rapid growth of various algae, which can have several undesirable consequences: reduced transparency of the water, cutting off bottom plants from sunlight; formation of surface scums

that are unsightly, smell bad, and discourage recreation; the generation of unappealing taste and odor in drinking water; the creation of a concentration of dissolved organic material conducive to the support of various disease organisms that would not prosper in less rich waters; the alteration of the *relative* abundance of the various algal species present, with adverse effects on food chains established under the previous conditions; and the depletion of dissolved oxygen, with resulting loss of fish life when the algal overgrowths or blooms die off and decompose. [138]

How can oxygen-depletion arise from the overgrowth of plants, inasmuch as they must have produced as much oxygen in their lifetimes as is needed for their decomposition (see Chapter 3)? The answer is twofold. First, oxygen is continuously exchanged between water bodies and the atmosphere, and under many circumstances that exchange depletes dissolved oxygen to less than what it would otherwise be (not all the oxygen produced in the water stays in the water, and what leaves may not be completely replaced from the atmosphere). Second, dead algae often sink and, as they decompose, deplete the oxygen content of deeper layers of water where the oxygen content already tends to be lower than that of the surface layer. (There is more oxygen near the surface because that is where most of the photosynthesis goes on and where oxygen enters from the atmosphere.)

The oxygen depletion is aggravated in many temperate-zone lakes by a phenomenon called *thermal stratification*. As discussed in Chapter 4, there is a warm layer of water at the surface in summer called the epilimnion, which is well mixed by the action of wind and waves and in which the temperature is almost uniform. Below the epilimnion is a layer called the thermocline, in which the temperature decreases 1° C or more for every meter of depth. The lowest layer contains the coldest water, is almost uniform in temperature, and is called the hypolimnion. (See Figure 11-15.) There is almost no vertical mixing in the thermocline and hypolimnion. The stratification is maintained because the density of water varies with temperature and the maximum density occurs at 4° C. Thus, as long as the coldest water in the lake is not less than 4° C, the coldest water will be on the bottom, slightly less cold (and hence less dense) water just above it, and so on.

A temperate-zone lake that is stratified this way gets

[138] For discussion of these effects, see American Chemical Society, *Cleaning our environment. The chemical basis for action*; W. T. Edmond son , "Fresh water pollution", in *Environment*, W. Murdoch, ed., Sinauer, Sunderland, Mass., 1975, pp. 251-271.

thoroughly mixed vertically twice a year. In the autumn, surface temperatures start to drop, eventually falling below the temperature of the deeper layers. Having thus become denser than the underlying layers, the surface water sinks. In freezing climates, the turnover process continues until the thoroughly mixed lake has been uniformly cooled to 4° C; as the surface water cools further, it no longer sinks because it then becomes less dense than the 4° C water below. The eventual result is a winter stratification with ice on top and water slightly above freezing below. Then, in the spring, the warming of the surface layer to the density maximum at

4° C causes that water to sink into the slightly cooler and less dense water below, and the lake turns over again.

Summer thermal stratification keeps oxygen-rich water at the surface from mixing into deeper layers; sustaining animal life in the deep water therefore depends on whether the supply of oxygen provided by turnover in the spring lasts until the next turnover in the autumn. If a lake is clear enough, some light penetrates to the hypolimnion so that the oxygen provided by the turnovers may be supplemented by photosynthesis there. Such oligotrophic lakes are clear, deep, and relatively low in plant life. Maintaining this condition depends on a shortage of nutrients. In eutrophic lakes, which have an abundance of nutrients, algal growth cuts off sunlight near the surface, and the decomposition of the dead organic matter raining down from above depletes oxygen in the hypolimnion, which can be replaced neither by photosynthesis (because there is no light) nor by mixing (because of stratification). As noted in Chapter 4, eutrophic lakes therefore cannot support populations of those species of fishes that require cold water, because in summer the deep, cold water contains no oxygen.

Natural processes cause all lakes to undergo the transition from oligotrophic to eutrophic over a long period of time. Specifically, the transition is brought about by the flow of nutrients in streams that drain the surrounding area, with the effect not only of enriching the organic content of the lake water but also of filling the lake gradually with dead organic matter that settles on the bottom. This natural transition is called eutrophication. The same term has been given to the acceleration of the process that takes place when the activities of civilization lead to substantial increases in the flow of nutrients into a lake. In everyday usage the term has become synonymous with *overfertilization* of any body of water--lake, river, estuary, bay, or near-shore ocean waters. The specialist's term for overfertilization of a body of water due to human activity is *cultural eutrophication*.

Several anthropogenic pathways to water exist for both nitrogen and phosphorus (see also Chapter 3). Both substances are applied to fields in inorganic form in fertilizer, [139] and both are present in sewage and in the wastes from livestock feedlots. Nitrates originating in vehicle exhausts fall in the rain, and phosphates added to detergents to improve their "cleaning power" become ingredients of municipal waste water. Neither nitrates nor phosphates are removed effectively from sewage by primary or secondary treatment plants. [140]

Phosphorus is the limiting nutrient in the growth of aquatic plants in far more circumstances than nitrogen is. One reason for this is that some aquatic plants (including blue-green algae) can convert atmospheric nitrogen that has become dissolved in the water into usable chemical form. The growth of those plants is unlikely to be limited by lack of nitrogen. The other major reason is that nitrogen compounds are in general much more soluble than phosphorus compounds, so the former migrate much more readily through soil and into waterways. The higher mobility of nitrogen compounds leads to much greater concentrations of nitrogen than of phosphorus in most natural bodies of water--enough so that phosphorus is the limiting nutrient for plant growth.

Because phosphorus compounds are so tightly bound to the soil, even very heavy fertilization does not lead to the leaching of much phosphorus into groundwater and surface water. Fertilizer phosphorus that reaches waterways does so almost entirely by being carried along in eroded soil

particles. Even in the water, most of that phosphorus remains in suspension (not in solution) so it is not readily accessible for use by aquatic plants. By far the largest source of soluble phosphorus in waterways is municipal sewage, which contains phosphorus both from excrement and from detergents. [141]

[140]American Chemical Society, *Cleaning our environment*.
[141]SCEP, *Man's impact on the global environment*, p. 146.

Many examples of the cultural eutrophication of lakes, due mainly to phosphorus additions in sewage, have been documented. [142] Some of them, such as Lake Washington in Seattle, some of the lakes around Madison, Wisconsin, and Lake Onondaga in New York, have made dramatic recoveries when citizen action has stopped the sewage discharges or restricted the use of phosphate detergents. [143]

The most famous example of advanced cultural eutrophication, Lake Erie, has been less fortunate. The streams that feed Lake Erie drain a large area that is heavily populated, highly industrialized, and intensively cultivated. Controlling the sources of phosphorus over such an area would be an enormous undertaking. The lake itself is relatively shallow (66 meters maximum depth, compared to between 230 and 406 meters in the other Great Lakes), and a thick layer of muck on the bottom contains vast quantities of nutrients that under appropriate conditions might redissolve into the lake. Large algal blooms are so common in Lake Erie, that only a few days after the onset of thermal stratification in the summer the oxygen in the hypolimnion is essentially gone. [144] The relative abundance of fishes in the lake has undergone a drastic transition over the past fifty years, characterized by replacement of species highly valued by people as food (lake trout, walleye, blue pike) with species considered less desirable (alewife, carp, sheepshead). Some of the changes in fish populations have been brought about not by cultural eutrophication alone, of course, but by the combined effects of eutrophication, the introduction by people of the sea lamprey and the alewife, and the heavy pollution of the lake with pesticides, industrial chemicals, and heavy metals. [145] Lake Erie is not dead, but it clearly is suffering from premature old age combined with a case of chronic poisoning. Unless it somehow proves possible to prevent permanently the resuspension of the inventory of toxins and nutrients in Lake Erie's bottom sediments, its condition--unlike those of smaller lakes--will not be reversible.

Although the best known and probably most serious examples of cultural eutrophication are lakes, rivers and estuaries are not immune to the problem. In a major ten-year survey of the twenty-two most important rivers and harbors in the United States (ranked by length and volume for rivers and by size of adjacent populations for harbors), 84 percent of the sections sampled exceeded phosphorus and phosphate concentrations associated with potential eutrophication, and 54 percent showed an increase in those concentrations between the period from 1963 to 1967 and the period from 1968 to 1972. [146] Nitrate concentrations exceeded those associated with potential eutrophication in 25 percent of the sections sampled and had increased between the two periods in 74 percent of the sections. Contrary to a fairly widespread impression, the circulation patterns

in typical estuaries, and even those along open ocean coastlines, are not conducive to rapid mixing of pollutants into the deeper water offshore; therefore, cultural eutrophication of those ecologically crucial regions is not a problem that can be ignored safely. [147]

Even though phosphorus rather than nitrogen is most often the governing nutrient in cultural eutrophication, overuse of inorganic nitrogen fertilizers may prove to be the greater environmental hazard for other reasons. One reason is that runoff of nitrates into surface- and groundwater supplies can lead to concentrations great enough to pose a direct toxic danger to the health of animals and human beings, both as methemoglobinemia and as a potential carcinogen (see Chapter 10). Secondly, the accelerated release of nitrous oxide (N_2O) into the atmosphere may in time adversely affect the ozone layer (as discussed below) with implications for human health and future food production. A further reason for concern about the prevalent pattern of using nitrogen fertilizer is the effect of those practices on soil humus, which is essential to the natural nitrogen cycle (see Chapter 6).

Humus, the organic matter in soil, is a poorly understood complex of compounds of high molecular weight. In natural soils inorganic nitrogen normally constitutes less than 2 percent of the nitrogen present. Most of the nitrogen is tied up in the large organic molecules of humus, which are derived from such varied sources as the fibrous remains of woody plant tissues, insect skeletons, and animal manure. The presence of humus makes the soil a favorable medium for the complicated chemical reactions and mineral transport needed for the growth of higher plants. Bacteria in the soil decompose humus to form nitrates and various other nutrient substances required by plant roots.

Roots require oxygen in order to take up nitrates and other nutrients, but oxygen is not available if the soil is tightly compacted, nor is water absorbed well. Thus one important function of humus is to maintain the porosity of soil, which permits oxygen to penetrate to the roots of plants and promotes the retention of water. Greater capacity to absorb and hold water reduces runoff and soil erosion after heavy rain and prolongs the retention of soil moisture during times of

drought. On several counts, then, humus is essential for the healthy growth of plants, and particularly (as experienced farmers know) for good crops.

In natural soil systems the nitrogen cycle is tight; not much nitrogen escapes to the atmosphere or is removed from the soil by leaching or surface runoff. It has been shown experimentally (as well as by centuries of farming experience) that by maintaining the supply of humus the fertility of soil can be perpetuated. This is not possible when fertilizers containing inorganic nitrogen are employed, unless organic carbon (in such forms as crop residues, sawdust, or straw) is supplied to the microorganisms in the soil. The undesirable decline of humus, which often occurs under heavy inorganic fertilization, is due to the failure of farmers to return crop residues (and thus carbon) to the fields. The decline is not caused by any deficiency in the fertilizers themselves. Indeed, if carbon is supplied in the proper proportion to inorganic nitrogen, the supply of humus can be increased and the quality of the soil improved.

If attempts are made to maintain soil fertility by continued applications of inorganic nitrogen fertilizers alone, the capacity of soil to retain nitrogen is reduced as its humus content drops. In humus, nitrogen is combined into nonsoluble forms that are not leached from the soil by rainwater. Depletion of humus "loosens" the soil cycles and permits large amounts of nitrate to be flushed readily out of the soil. Only about 50 to 60 percent of the applied nitrogen is incorporated into the crops. [148] This loss plus depletion of the original humus leads to the need for more and more fertilizer, in a vicious circle.

The serious consequences of such human interventions in the nitrogen and phosphorus cycles call for strong remedial measures. The only successful steps against phosphorus pollution that had been taken in the United States as of 1975 were restrictions on the phosphorus content of detergents, a few local bans on the sale of phosphorus-containing detergents, and diversion of sewage and industrial wastes from a number of acutely suffering lakes. [149] With specific regard to nitrogen, there are only restrictions on the nitrate levels in foods. Much more systematic measures are required, the most important of which would be closing the open nitrogen and phosphorus cycles of agriculture by returning the organic "wastes"--now contributing to the pollution problem--to the soil.

Human excrement, for instance, is considerably richer in both nitrogen and phosphorus than cattle manure. In the People's Republic of China, human waste is carefully collected and used largely untreated, along with manure and agricultural wastes. These organic fertilizers still comprised about half of China's total fertilizer applications in the early 1970s. [150]

The direct use of human (or livestock) waste as fertilizer presents opportunities for the transmission of many diseases and parasites. Some methods of treatment, such as aerobic or anaerobic digestion by bacteria, however, appear to prevent this, at least for most fertilizing purposes. Treated sewage water and sludge (the concentrated residue that settles out of sewage water) is used successfully as fertilizer in many parts of the world, including the United Kingdom, Australia, Fed-

[148] G. Stanford, C. England, and A. Taylor, *Fertilizer use and water quality*.

[149] An account of the national brouhaha over detergents in the early 1970s (from a predominantly probusiness viewpoint) can be found in William S. Rukeyser, *Fact and foam in the row over phosphates*.

[150] John Sigurdson, "Resources and environment in China", *Ambio*, vol. 4, no. 3, pp. 112-119, 1975.

eral Republic of Germany, and a few places in the United States. [151] At least one operating plant in the United Kingdom, run by the local water authority, sells recovered water to industry and treated liquid and driedsludge fertilizer to local farmers. It uses the sludge gas produced by the digestion process to generate electricity that runs the plant, a nearby sewage pumping station, and an incinerator, and cooks meals for a group of senior citizens. "Waste" heat from the generators is used for the digesters. [152] Although the costs of collecting, treating, and distributing sewage have been a major obstacle to using it as fertilizer, this system apparently costs little more than conventional sewage-disposal methods.

In the United States, the manure of cattle produced on feedlots alone far exceeds in volume that produced by the human population, even though phosphorus and nitrogen concentrations are lower. [153] The nutrients in that material, as well as manure from similarly managed chickens and pigs, also could and should be returned to the soil. Some 80 to 90 percent of these animals are in feedlots for part or all their lives. In the past, huge volumes of feedlot sewage were discharged into rivers, causing severe pollution. The EPA has made reduction of pollution from that source to zero by the mid- 1980s a goal, which should provide incentive for alternative uses. If all feedlot sewage in the United States were used for fertilizer, it would provide more than enough for all U.S. acreage planted in corn. [154] If augmented with municipal sewage, garbage, and other wastes, it would, of course, go even farther.

Other potential sources of organic fertilizing nutrients include agricultural wastes (some of which can also be used as livestock fodder), treated garbage, and foodprocessing wastes. Most of these presently are wasted: they are discharged in waterways, put in landfill, or burned in incinerators. The values of these materials as fertilizer must, of course, be balanced against their values for other uses, such as supplementary livestock feed and energy sources, taking into consideration the energy and other costs of the alternatives. But it is clear that merely throwing them away and then cleaning up the mess (both costly and energy-consuming exercises) is the east intelligent solution.

The most promising method of recovering and recycling the nutrients from manure, human sewage, crop residues, and other organic wastes--while deriving energy as well--is with biogasification plants like the one described above (also discussed in Chapter 8). Such facilities, which can range in size from backyard digesters to large factories, have the dual advantage of producing needed fuel from the hydrocarbon content of the wastes and leaving the nitrogen, phosphorus, and other nutrients behind in a residue much more compact than the original wastes. Thus, transportation costs and handling problems associated with using those residues as fertilizer should be less than those of using the uncompacted raw material. The prospects that this approach can compete economically with using inorganic fertilizers are improved by the rising cost of the latter, particularly the very energy-intensive inorganic nitrogen fertilizer whose cost is

closely tied to the cost of energy. Even if fertilizer from organic wastes should turn out to be more expensive at first than inorganic fertilizers, however, its use should be strongly encouraged by regulations and subsidies, in recognition of its ecological advantages.

The U. S. National Aeronautics and Space Administration (NASA) has recently been conducting experiments using water hyacinths to purify waste water. These aquatic plants, generally considered a pest in warm regions around the world, have proven remarkably efficient at absorbing nutrients and other pollutants from sewage water. The dried plants then can be used to make biogas and/or for fertilizer or livestock feed. [154a]

Naturally, care must be taken to control the new problems that innovative approaches to old problems often bring. (When phosphorus was discredited on ecological grounds as an ingredient in detergents, for example, one of the first substitutes that was tried was NTA--nitrilotriacetic acid. Then evidence appeared that

that compound was a potent mutagen, and its use was discontinued. [155]) The precise effects on soil organisms of fertilizing with various kinds of manure are not yet known, although they are being investigated. Results of comparing yields under different fertilizing regimes--all organic, all inorganic, or a combination--in small, controlled studies indicate that the mixed approach may be best for many crops. [156] Perhaps the most serious potential problem associated with continuously recycling nutrients by means of biogasification and application of the residues as fertilizer is accumulation of toxic heavy metals, whose concentration could increase at each cycle. While trace amounts of many of these--copper, cadmium, cobalt, for instance-are essential to life, high concentrations accumulated in soil and concentrated by crops can be deadly. Some experimental schemes for processing urban sludge are attempting to remove these and other toxic substances to be recycled in industry. Better yet, the industries themselves should be encouraged to remove such toxins before discharging them into waste water. In LDCs, most people still live in rural areas, which would minimize both the problem of transporting their wastes to farms and the likelihood of significant pollution with heavy metals or other toxic materials.**Thermal pollution.** The term *thermal pollution* is most commonly used to describe the discharge of waste heat from thermal generation of electric power or from industrial processes into natural bodies of water. The ultimate fate of this energy--and of all other energy mobilized by human activity--is to find its way into the atmosphere and from there into space. The atmospheric aspects of this more general "heat problem" are considered later; here we consider only the effects of heat deposited directly into aquatic ecosystems.Aquatic thermal pollution has been the focus of much research and considerable controversy. Some of the controversy has

arisen because the effects are so different at different sites. Even very large power plants can discharge their heat to the ocean with minimal effect where deep water lies close to shore and where the local surface and underwater topography permit good mixing of heated effluent with colder water. Undoubtedly, there are even circumstances where the heated effluent can be beneficial--for example, in accelerating the growth of shellfish. [157] On the other hand, large discharges of waste heat in bays or estuaries where mixing is poor can produce serious problems, as is also often the case in rivers and lakes. Documentation of the adverse effects has led to the widespread use by power plants of cooling towers to transfer the waste heat directly to the atmosphere (see Chapter 8).Among the most important adverse effects of a temperature increase that affects a substantial part of a natural body of water are: [158]

The dissolved oxygen content of the water falls, reducing the capacity of organisms in the water to detoxify chemical wastes.

The diminished oxygen content places a stress on aquatic organisms, which is compounded because the elevated temperature raises their metabolic rate and hence their need for oxygen. (As a rough average, metabolic rate doubles for every 10° C rise in temperature.) [159]

A large temperature increase can kill some organisms outright, while producing biochemical changes that prevent others from reproducing or increase their susceptibility to toxic substances. [160] Temperature changes due to repair, refueling, or normal cycling of a power plant can greatly reduce the possibility of a biota's adapting to a new temperature regime. Species of fishes and plants most tolerant to heat often are the least desirable from the human point of view, such as rough fishes and the blue-green algae most responsible for taste and odor problems in municipal water supplies. The role of temperature in determining what species are present is suggested by the data in Figure 11-16.

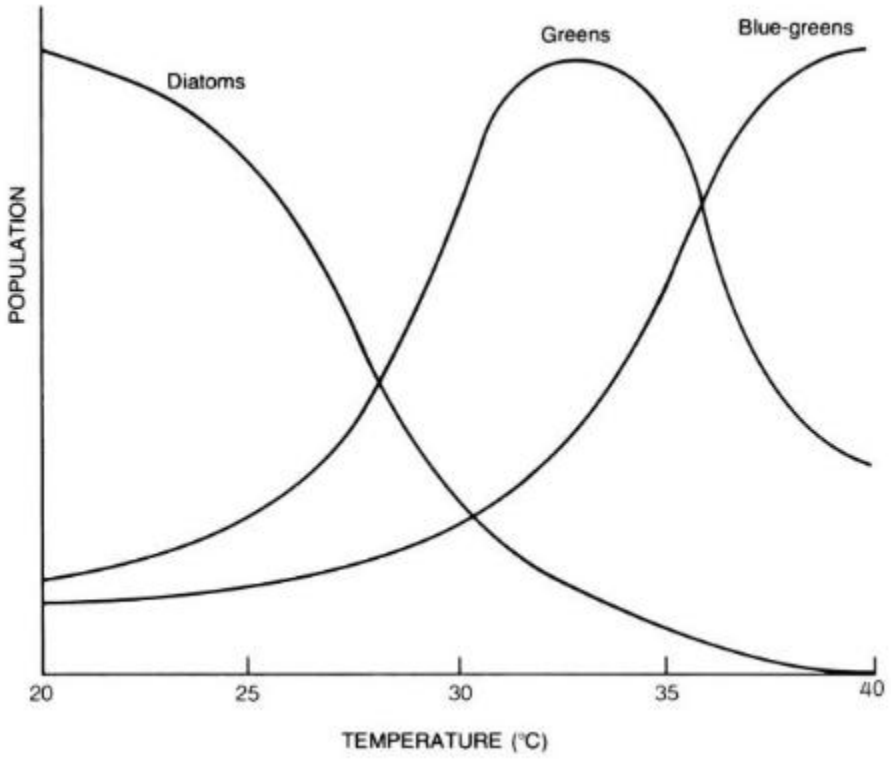
[158] A good survey is C. A. Carlson, Jr., *Impact of waste heat on aquatic ecology*. See also John R. Clark, *Thermal pollution and aquatic life*.



[159] G. Masters, *Introduction to environmental science and technology*, Wiley, New York, 1974.

[160] Effects at high temperatures are illustrated in J. W. Gibbons and R. R. Sharitz , eds., *Thermal alteration of aquatic ecosystem*.

Other effects that may be significant in some circumstances are alteration of the thermal stratification and time of turnover of thermally stratified water in lakes (which can affect productivity and species composition), and increased rates of evaporation from heated bodies of water. The Environmental Protection Agency recommends, in order to minimize the magnitude of adverse effects, that waste-heat discharges from such facilities be managed in such a way that the maximum temperature rise after mixing not exceed 5°F in streams, 3°F in lakes, 4°F in coastal marine environments in winter, and 1.5°F in coastal marine environments in summer. [161]

Radiation and the structure of ecosystems. Ecosystemic effects of radiation have been investigated through the use of chronic irradiation as a perturbing influence in experiments on

natural ecosystems. The experiments employed powerful sources of radiation (9500 Ci cesium-137, 3000-4000 Ci cobalt-60) that exposed adjacent parts of an ecosystem to thousands of roentgens per day and areas progressively farther from the source to doses that declined roughly as the square of the distance. [162] The general results of such experiments in oak-pine forest, the lichen flora of that forest, and the herbaceous flora of an old field produced the following generalities. The structure of the community changed as upright plant forms were differentially damaged and prostrate forms were placed at a relative advantage. Dominant forms replaced one another along the gradient of radiation dosage as they do along natural environmental gradients, diversity declined with increasing dosage, and usually (but not always) net production decreased with increased dosage. [163] These changes are quite similar to those produced by other gradients of environmental stress, such as increasing altitude on mountains, approach to the spray zone on seashores, decreasing rainfall as the edge of the desert nears, or nearness to an iron-sintering plant (as described in the

preceding text). The reasons for these patterns are not completely understood, but they seem to be related to changes in the production/respiration ratio in various segments of the community. For instance, trees are limited in size because, as they grow, the proportion of bark, which contributes heavily to respiration, increases compared to that of photosynthetic leaves. Stresses tend to decrease photosynthesis rather than respiration; therefore they affect trees more than smaller plants, which do proportionately less respiring. [164]

Structural changes in vegetation also change nutrient patterns and inevitably have a dramatic impact on the fauna. Like other pollutants, radioisotopes are concentrated by food chains--for instance, cesium-137 has been found to double in concentration with each step in Alaskan lichen

→ caribou → wolf (or Eskimo) food chains, and plutonium concentrations in algae of 1000 to 6000 times that of their environment have been measured. [165]

In general, ecologists tend to feel that genetic disturbances from radiation exposure in nonhuman populations of both plants and animals are not serious; they assume that selection will compensate for them. Effects of radiation on animals are diverse, but some generalizations are possible. For animal populations, the major stress seems to be effects on reproductive processes rather than shortened lifespans. Long-lived species are more sensitive to radiation than short-lived ones; therefore, since predators are generally longer-lived than herbivores, they would be differentially removed from irradiated ecosystems. [166] In this way, radiation effects may be very similar to those of pesticides.

It would appear that potential levels of radiation releases from nuclear-power enterprises, which are of great concern because of their direct effects on humanity, would probably have little serious effect on other components of ecosystems. On the other hand, in the aftermath of thermonuclear war, radiation could be one of the major stresses on Earth's ecological systems.

ATMOSPHERE AND CLIMATE

The complicated geophysical machinery that governs weather and climate is described in Chapter 2. The more carefully this machinery has been studied, the more intricate and, in many instances, delicately balanced it has seemed to be. The complexity and possible fragility of atmospheric and related climatic phenomena mean that the possible avenues of significant human intervention are many. They include changing the abundance of atmospheric constituents that govern the atmosphere's transparency to solar and terrestrial radiation (for example, by adding carbon dioxide, particles, water droplets and water vapor, and by destroying ozone), altering the characteristics of the interface between the atmosphere and land or sea (for example, by agriculture, urbanization, deforestation, desertification, and oil spills), and perturbing natural energy flows with the release of heat from industrial activities.

It cannot yet be said that atmospheric processes, weather, and climate are thoroughly understood, even exclusive of the growing perturbations caused by the activities of civilization. Not surprisingly, then, the actual magnitude and present and future consequences of such human perturbations cannot be accurately and unambiguously stated even as individual effects, much less in combination. It is not even known whether all the important potential effects have been identified--not to mention quantified. The sudden emergence in 1974 and 1975 of the probable role of spray-can propellants as a threat to the ozone layer is indicative of the sorts of further surprises that may yet be in store.

Clearly, the fact that knowledge of the possibilities is incomplete is anything but grounds for complacency. Enough is already known to make plain that civilization has become a force large enough *in theory* to disrupt atmospheric processes and climate not only on regional but on hemispheric and even global scales. That technological civilization has reached a level of activity that implies significant potential influence over global processes so crucial to well-being, without commensurate understanding or control, should appall any thoughtful person. In the following text we survey some of the more important mechanisms for human intervention in atmo-

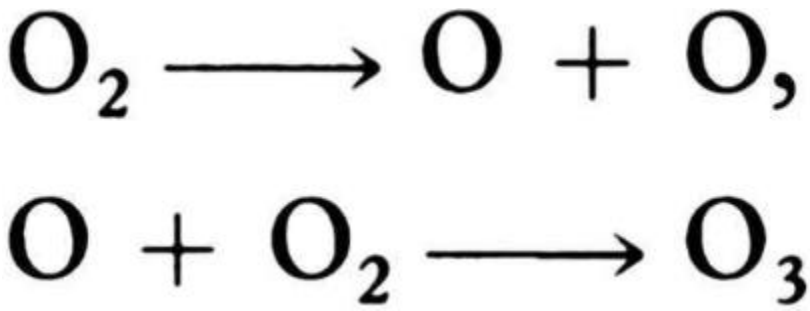
sphere and climate, beginning with the threats to the ozone layer that became really credible only in the mid-1970s. [167]

Threats to the Ozone Layer



In the atmosphere at sea level, only about I molecule of 100 million is ozone (chemical formula O_3). Most of the small atmospheric pool of this compound is concentrated, however, in the part of the stratosphere lying between 15 and 40 kilometers altitude. In that region the molecular concentration of ozone reaches about 15 parts per million. [168] That is still only a trace, but it is enough to play a crucial role in the interaction of the atmosphere with incoming sunlight. In particular, atmospheric ozone is the only effective shield of Earth's surface against ultraviolet solar radiation in the range of wavelengths that are damaging to plants and to animals, as discussed further below. Moreover, the absorption of this radiation in the stratosphere and consequent heat production there are responsible for the stratospheric temperature inversion that suppresses mixing of the lower atmosphere (troposphere) with the air at the higher altitudes. This fact, and the mere circumstance that the absorbed energy does not reach Earth's surface, certainly have some effect on world climate.

The stratospheric pool of ozone is the result of a balance between continuous processes that produce and destroy this substance. (The size of the pool varies with latitude and with time in response to a variety of natural factors.) Production takes place when molecular oxygen (O_2) is split by ultraviolet solar radiation and the resulting oxygen atoms (O) attach themselves to other oxygen (O_2) molecules:

$$O + O_3 \longrightarrow O_2 + O_2$$

$$2O_3 \longrightarrow 3O_2.$$

Destruction takes place by means of several different reactions, in which the net results are either or

The destruction reactions proceed most rapidly in the presence of certain catalysts: the hydroxyl radical HO (which comes from water vapor in the stratosphere), nitric oxide (NO), and atomic chlorine (Cl). [169] All of them are scarce in the natural stratosphere, although crucial to its chemistry. Activities of civilization that change the stratospheric concentrations of these catalysts also change the rate at which ozone is destroyed, thereby altering the production-destruction equilibrium and possibly reducing the stratospheric pool of ozone.

SSTs and nuclear war. The first specific threat to the ozone layer to be taken seriously by people in the technical community was the proposed operation of a fleet of supersonic transports (SSTs). An early concern was that the water vapor introduced into the stratosphere in the exhausts of those aircraft would cause a reduction in ozone by increasing the stratospheric concentration of HO. [170] This particular concern subsequently proved to be misplaced; the real hazard to ozone in SST exhausts is nitric oxide, which is a much more effective catalyst for the ozone-destruction reactions than HO. A paper published by chemist Harold Johnston of the University of California at Berkeley in 1971 indicated that the nitric oxide emitted by a fleet of 500 SSTs of the U.S. design could reduce the stratospheric ozone concentration by an average of 20 percent, with local peak reductions up to 50 percent. [171] This finding was strongly attacked by SST proponents, but a combination of further research and exhaustive reviews by panels of experts under the

---

[167] An excellent reference--authoritative but aimed at the intelligent lay person rather than at the specialist--providing more extended discussion of the entire set of issues surrounding human intervention in atmosphere and climate is S. H. Schneider with L. E. Mesirow, *The genesis strategy*.

[168] A good review of the data on the natural distribution of ozone is given in H. S. Johnston, "Photochemistry in the stratosphere--with applications to supersonic transports".

[169] A much more comprehensive treatment of ozone chemistry is P. J. Crutzen , "Estimates of possible variations in total ozone due to natural causes and human activities". See also C. E. Kolb, "The depletion of stratospheric ozone".

[170] The direct effects of the added water vapor on the transmission of radiation by the stratosphere also have to be considered. See below, and SCEP, *Man's impact*, pp. 64-74.

[171] H. S. Johnston, "Reduction of stratospheric ozone by nitrogen oxide catalysts from SST exhaust". The other pioneer in the identification of this threat was P. J. Crutzen (see, for example, his "The influence of nitrogen oxides on the atmospheric ozone content".)

auspices of the National Academy of Sciences and the United States Department of Transportation completely substantiated Johnston's work. One of the reviews, by the Climatic Impact Assessment Program (CIAP) of the Department of Transportation, produced a final report written so obscurely that some journalists misread it as a refutation of Johnston's results; and a few made fools of themselves in nationally syndicated columns decrying the "environmental hysteria" that had stopped the SST. [172] Most of the confusion caused by the CIAP report was caused by the prominence it gave to the conclusion that a somewhat smaller fleet of the lowerflying, smaller-engined Concorde SSTs would not significantly disrupt the ozone layer, while it buried the confirmation of Johnston's conclusion about 500 U.S. SSTs in the fine print. [173]

Nuclear bombs offer an additional avenue by which significant amounts of nitrogen oxides can be added to the stratosphere. The high temperature in nuclear fireballs produces nitrogen oxides in abundance from atmospheric nitrogen and oxygen, and much of that material is deposited in the stratosphere. Although there is some controversy about the issue, several investigators believe that ozone depletion by atmospheric bomb tests conducted in the early 1960s was great enough (around 5 percent) to show up in the relatively crude historical data that are available for stratospheric ozone concentrations. [174] Although depletion of ozone may seem at first glance to be the least of humanity's worries if a large nuclear war ever took place, that is not really so obvious. In some circumstances, the global depletion of ozone might have a greater effect on noncombatant nations distant from the conflict than would radioactive fallout. [175]

Chlorofluorocarbons. It was known as early as 1973 that free chlorine in the stratosphere would be an even more efficient catalyst than nitric oxide for destruction of ozone, but since no source of free chlorine that could reach the stratosphere was known at that time, little concern was expressed about this phenomenon. It was shown in 1974, however, that a class of compounds variously known as chlorofluorocarbons, fluorocarbons, and Freons could be dissociated by wavelengths of sunlight present only in the stratosphere, to release free chlorine. [176] Those compounds have been used very widely as refrigerants and as propellants in some aerosol spray cans. The most common ones have the chemical formulas $CFCI_3$ and CF_2Cl_2. They are essentially inert to chemical reaction and relatively insoluble in water. The result of these properties is that virtually the total amount put into the atmosphere remains there, chemically intact, until it reaches the stratosphere.

The amount of chlorofluorocarbons thought to have reached the stratosphere by late 1974 was only enough to have caused about a I percent decrease in the ozone--a change too small to be detected by existing techniques. Production of those compounds has been growing rapidly, however; in this situation, a large fraction of the amount ever produced has been produced only recently and has not had time to diffuse up to the stratosphere. (Recall from Chapter 2 that the mixing time between troposphere and stratosphere is a few years.) Some calculations have indicated that ozone depletion due to catalytic destruction by chlorine from chlorofluoromethanes could reach 5 percent by 1990, even if production of those compounds had been halted at the end of 1975, and around 15 percent by the year 2000 if production continued to grow at 10 percent per year. [177]

There are many approximations in such calculations, and more precise analyses and measurements were underway as this text was being written. The available information gives ample cause for serious concern, however, a position underlined by a federal scientific task force that reviewed the issue in mid-1975. [178] Assertions

[172]The CIAP report itself is A. Grobecker, S. Coroniti, and R. Cannon, *The effects of stratospheric pollution by aircraft*. The more forthright of the two major scientific reviews of the question in the United States is National Academy of Sciences, *Environmental impact of stratospheric flight*.

by the industries producing chlorofluorocarbons that no action should be taken to curtail production until proof of harm is persuasive *to them*, are so irresponsible as to defy imagination.

Nitrogen fertilizer. The man-made threats to ozone discussed so far--SSTs, nuclear bombs, and aerosol propellants and refrigerants--share the characteristic that human well-being does not depend in any fundamental sense on the use of the offending products. SSTs are not economically necessary, harmless substitutes can be found for most applications of chlorofluoromethanes (modifications of the finger-operated spray pump familiar in window-cleaner bottles could handle most aerosol-can applications), and it should be plain that nuclear bombs are a product the world can do without. Thus, the future magnitude of those threats *could* be limited without serious social cost merely by the exercise of good sense--that is, by not producing or using them any longer. An intrinsically more difficult problem is posed by the possibility that nitrogen fertilizer is the source of yet another threat to ozone. As Orville Freeman, former U.S. Secretary of Agriculture, has pointed out: "A world without fertilizer would be a world without the capacity to sustain a billion of our fellow human beings." [179]

The danger is that nitrous oxide (N_2O) produced from nitrates and nitrites in soil or water by denitrifying bacteria (see above in this chapter and Chapter 3) is oxidized in the upper atmosphere to ozone-destroying nitric oxide. Applying more nitrogen fertilizer may add more nitrous oxide to the atmosphere, which means more nitric oxide in the stratosphere, which means less ozone. The intrinsic difficulty is the apparent reliance of immediate prospects for increased

food production on greater use of nitrogen fertilizer. This threat to the ozone is less certain at this writing than the others discussed here, because of uncertainties in the atmospheric chemistry of N_2O and in the magnitude of flows in the natural nitrogen cycle. [180] Some models of the processes at work suggest that ozone depletion from this cause is likely to be small and gradual.

If the worst proves to be true, however, forecasted increases in the use of nitrogen fertilizer could produce a *15-percent reduction* in stratospheric ozone by the year 2025. That prospect would pose an agonizing dilemma; unlike its relationships to SSTs, bombs, and spray cans, civilization is *really* hooked on nitrogen fertilizer. At the very least it is another argument in favor of using nitrogen fertilizers so they are maximally effective and minimally wasted, and for relying as much as possible on natural fertilizers (from which relatively little nitrogen "leaks" to the atmosphere.)

Other threats to ozone. There may be other compounds as dangerous to the ozone layer as those already mentioned, or more so. Carbon tetrachloride (CCI_4), for one, is added to the lower atmosphere by processes both natural and human. There is evidence that human activity is the principal source, and that a significant quantity of the carbon tetrachloride reaches the stratosphere. [181] It is conceivable that chlorination of drinking water and of sewage are important sources that have some effect on ozone. Bromine is known to be an even more efficient catalyst for the destruction of ozone than chlorine; bromides are used in gasoline additives, agricultural chemicals, and flame-retardants. Pathways to the stratosphere for bromides have not yet been evaluated. Alkali metals such as sodium and potassium might destroy ozone if added to the stratosphere by nuclear explosions over oceans or by intentional seeding as a chemical/climatological weapon. [182] Many of these possibilities may prove to be false alarms, but, as in Russian roulette, only one "loaded" possibility may be too many.

Consequences of ozone depletion. The existing ozone layer screens out more than 99 percent of incoming solar energy in the wavelength region between 0.23 and 0.32 microns; radiation of those wavelengths is harmful to most forms of terrestrial life, and the small fraction that gets through is known to cause sunburn, skin cancer, and eye damage in human beings, as well as various kinds

[179] Quoted in *Chemical and Engineering News*, June 17, 1974, p. 13.

of damage to other animals and plants. [183] Most scientists agree that terrestrial life did not evolve until the ozone layer was established. The special effectiveness of ultraviolet radiation in damaging living systems is due to the sensitivity of the genetic material DNA and of proteins to those wavelengths. DNA exhibits a resonance--the capacity to absorb radiant energy very

efficiently--at wavelengths around 0.265 microns. Proteins typically have resonances in the range of 0.275 to 0.285 microns. The energy absorbed when radiation of those wavelengths strikes the DNA and protein molecules damages them, causing the many disruptive effects now known, and probably others as well.

Analytic and computer models of varying degrees of sophistication have been used to estimate what increase in the ultraviolet radiation reaching the surface would be associated with different degrees of depletion of the stratospheric ozone. [184] Although the relation between ozone depletion and increased ultraviolet at the surface varies with latitude and other factors, a rough average is that a 5-percent decrease in ozone produces a 10-percent increase in radiation. The best-studied effect of such an increase is an increase in the incidence of human skin cancers, the magnitude of which is estimated to be about equal to the percentage change in radiation. Thus a 5-percent decrease in ozone and a 10-percent increase in ultraviolet radiation would produce 20,000 to 60,000 additional skin cancers per year in the United States alone, and perhaps 5 times as many worldwide. (Incidence of skin cancer is higher among light-skinned people than among dark-skinned.) [185] About 5 percent of the skin cancers would be fatal. A 30-percent reduction in ozone would be expected to produce on the order of 1 million additional skin cancers per year worldwide, of which perhaps 50,000 would be fatal.

Although an increase in skin cancer is the best understood of the effects of ozone depletion, it is by no means the only and not necessarily even the most serious such effect. Laboratory tests have indicated that increased ultraviolet radiation impairs the growth of certain crop plants and adversely affects a wide variety of organisms from bacteria to vertebrates. Phytoplankton, the primary producers at the base of oceanic food webs, may prove especially vulnerable if the light-receptors that trigger the protective dive response to excess radiation are not sufficiently sensitive to ultraviolet light. Furthermore, many insects "see" ultraviolet light and rely on it for navigation; interference with their pollination function is but one of several conceivable consequences for insects of an increase in ultraviolet intensity. Acceleration of the mutation rate of microorganisms because of DNA's sensitivity to ultraviolet could have adverse effects on human beings through disease, causing more frequent development of strains of microorganisms against which people would have no resistance and of strains resistant to antibiotics. The consequences for ecosystems of differential susceptibility among different organisms to increased ultraviolet radiation cannot be predicted with any accuracy, but such differential susceptibility is known to exist and the possibility of its resulting in serious instability cannot be excluded. [186]

Nonbiological damage from increased ultraviolet radiation is likely to include faster deterioration of paints, fabrics, plastics, and other materials. The magnitude and economic cost of such effects is uncertain--and dependent on the amount of increased radiation--but it would surely be significant.

Probably least certain of all is the impact of ozone depletion on climate. The situation is extremely complicated: ozone absorbs and reradiates radiant energy in the infrared part of the spectrum of wavelengths as well as in the ultraviolet part; so do products of some of the reactions that consume ozone, and so do most of the catalysts for the ozone-destroying reactions and their precursors (chlorine is such a catalyst, the chlorofluorocarbons are its precursors). One

recent study based on a relatively simple model found it possible that continued growth of chlorofluorocarbon production could produce

a significant global warming by the year 2000, independent of the effect on ozone, merely because of a greenhouse effect in which those compounds would block outgoing infrared radiation. [187] Changes in the radiationabsorbing and -emitting properties of the atmosphere not only change the direct radiation flows at Earth's surface, however; they also change the vertical temperature distribution in the troposphere and the stratosphere, which in turn changes the rate of vertical circulation. [188] All of this could influence climate in ways that as yet defy detailed prediction.

Climate Change Through Surface Modification

Whereas the importance to climate of processes high in the stratosphere has been appreciated only relatively recently, the relevance to climate of the condition of Earth's surface is more obvious. The most important features are: (1) presence or absence of water, (2) reflectivity, or albedo, (3) ability to transfer water to the atmosphere, (4) capacity to store heat, and (5) topography and texture. These interrelated features determine how much of the incident radiant energy is captured, how it is apportioned between surface and atmosphere, how the surface interacts with the winds, and how the shoreline interacts with ocean currents. Civilization can influence the surface conditions by changing or removing vegetation, by damming and diverting rivers to form reservoirs and irrigation projects, by "reclaiming" land from shallow seas and bays, by covering land with pavement and buildings, by spilling oil on water, snow, and ice, and by releasing previously stored energy as heat.

Cities and heat. The most obvious and also the most localized such effects are those associated with cities. The differences in various aspects of climate between urban areas and adjacent rural environments are summarized in Table 11-4. The changes in climate are caused by urban heat, snow removal, accelerated runoff, altered albedo and heat-storage capacity resulting from replacing forests and fields with concrete and buildings, and the

TABLE 114 Avarage Changes in Aspects of Local Climate Caused by Cities

Aspect	Comparison with rural environment
Cloud cover	5%-10% more
Winter fog	100% more
Summer fog	30% more
Precipitation	5%-10% more
Summer relative humidity	8% less
Winter relative humidity	2% less

greater surface roughness. [189] The differences indicated in Table 11-4 have not necessarily all been bad, in the sense of causing harm; some may even have been beneficial. What is interesting is that they provide concrete evidence of quite dramatic human influence on local climates--influences that could become adverse in terms of (for example) agriculture, as urban settlements expand and exert their effects over larger areas.

Especially careful attention must be paid to the heat released in urban regions as both populations and energy use per person grow. This is the ultimate form of thermal pollution -- not just waste heat but the inevitable conversion of virtually all useful energy to an equal amount of heat, as predicted by the laws of thermodyamics (Box 2-3). The heat released by human activities in Manhattan -- more than 600 watts per square meter -- is about 6 times the natural net radiation balance in that region. [190] (The net radiation balance is incoming radiation minus outgoing radiation, a figure of particular climatic significance, as discussed in Chapter 2.) Over the much larger area of Los Angeles County -- about 10,000 square kilometers-the heat being released by human activities around 1970 was about 6 percent of the natural net radiation balance.

Various combinations of area covered and power density produced by human activities, both actual and hypothetical, are represented graphically in Figure 11-17. It is clear there that human energy use averaged over

Man-made power densities and area. Ten percent of the net radiation balance has been reached over areas of 10,000 square kilometers and I percent over areas exceeding 1,000,000 square kilometers. (After National Center for Atmospheric Research, *Atmospheric implications of energy alternatives*.)

all the continents is still more than 1000 times smaller than the natural radiation balance. However, a population of 6 billion people using energy at the rate per capita in Sweden in 1975 would be equivalent to almost 0.4 percent of the natural radiation balance on the continents, and a hypothetical society of 20 billion people using energy at the rate of 20 thermal kilowatts per person, as envisioned by A. M. Weinberg and P. Hammond, [191] would reach 2.6 percent of the radiation balance on the continents. Even if the latter energy use were evenly distributed over the land surface, it could probably produce significant changes in global climate; conceivably even the smaller amount could do so.

How does one reach this conclusion? The simplest models assume that human heat input is equivalent to a fractional increase in solar input, distributed over a uniform Earth. Straightforward calculation for this enormously oversimplified situation suggests that an increment of 1 percent of the average solar energy flow at the top of the atmosphere (that is, 3.4 watts per square meter, averaged over the whole globe) would produce an increase of about 0.7° C in mean global surface temperature. [192] (This model is described in Box 11-4.) Weinberg and

Hammond were reassured by this sort of result, since their 400-billion-kilowatt civilization averaged out to only about 0.8 watts per square meter of land and sea. Unfortunately the outlook is not really reassuring. Making the model slightly more realistic by accounting for some of the important effects of the atmosphere (instead of doing the calculations just for a solid body) increases the apparent sensitivity of global surface temperature to heat input by a factor of roughly from 2 to 4 -- that is, instead of 0.7° C from an increment of 3.4 wars per

[191]A. M. Weinberg and P. Hammond, "Limits to the use of energy".
[192]See, for example, J. P. Holdren, Global thermal pollution, in *Global Ecology: Readings toward a rational strategy for man*, John P. Holdren and Paul R. Ehrlich, eds.

BOX 11-4 Simplified Global Energy Balance and Civilization's Contribution

The simplest calculation represents Earth as a blackbody radiating heat into space at a rate corresponding to its mean surface temperature (T). The energy-balance formula corresponding to that assumption is $SC + M = SC\alpha + 4C\varepsilon\sigma T^4$.

The left-hand side of the equation represents the rate of input of energy to Earth -- the solar constant S multiplied by the cross section (*C*) that Earth presents to the sun, plus miscellaneous energy inputs (*M*), including tides, geothermal energy, and heat dissipation from human activities. The right-hand side represents the rate of output of energy from Earth; a represents the albedo, so SCα stands for the reflected sunlight; σ stands for the constant in the Stefan-Boltzmann radiation law; and ε represents the effective emissivity (basically a "fudge factor" that corrects for neglecting the effects of the atmosphere, which really does most of the Earth-atmosphere system's radiating to space, at a temperature of about 24° C lower than the average surface temperature, as described in Chapter 2). The factor of 4 in the radiation term is there because the total global surface area, which radiates, is 4 times the cross-sectional area (*C*).

The values of these parameters are as follows: $SC = 1.74 \times 10^{17}$ watts, *M* = 3.0 X 1013 watts (of which about 0.8×10^{13} watts was civilization's contribution, as of 1975), α = 30 percent, and $\sigma = 5.67 \times 10^{-B}$ if *T* is measured in degrees kelvin and *C* in square meters. Then, setting ε = 0.61 gives the observed surface temperature of 288°K, or 15°C.

The sensitivity of the temperature in the model to changes in the energy input can be obtained readily by elementary calculus. Let the amount of heat that must be radiated away, SC (1 -- α) + *M*, be denoted *R*. For temperature changes (A*T*) that are much less than the temperature's initial value of 288° K, one finds $\Delta T/T = 0.25\ \Delta R/R$, where Δ*R* is the change in the amount of heat that must be radiated away. This means that a 1-percent increase in the amount of heat to be radiated away produces an increase of 0.25 percent in surface temperature. That is, $\Delta T/T = 0.25\ (0.01) = 0.0025$, $\Delta T = 0.0025$ (288° K) 0.72° K.

Such an increase in average global surface temperature could be quite significant. The corresponding 1-percent change in the present value of *R* (1.22 x 1017 watts) would amount to an increase in the 1975 human energy use by a factor of about 150. That amounts to just over 7 doublings, a feat that would require about a century at a growth rate of 5 percent per year. Each doubling thereafter would double the temperature increment, so that to reach an unquestionably intolerable global average increase of 16 x 0.72 = 11.5° K (11.5° C, or 21° F) would require only an additional 4 doublings -- 56 years at 5 percent per year.

Calculations with so oversimplified a model are satisfactory for showing the impossibility on climatic grounds of long-continued exponential growth of human energy use. However, as noted in the text, the complexities of the atmosphere and the fact that human energy use is not evenly distributed over Earth's surface suggest that serious thermal disruption could occur much sooner than this simplest of energy-balance models indicates.

square meter, one might get 1.2° to 2.6° C. [193] Moreover, the complexities of atmospheric circulation are such that one would expect an average increase of, say, 1 degree, to be associated with much greater temperature changes in certain regions, such as near the poles. Wind and rainfall patterns could change drastically as a result.

What makes thermal disruption of climate an even more imminent possibility than the foregoing considerations suggest, however, is that civilization's heat inputs are distributed very unevenly over the land surface -- not uniformly, as all the simple models assume. A graphic illustration of this fact is provided in Figure 11-18, a satellite photograph of the central and eastern United States at night. Large, concentrated sources of heat can influence the atmospheric long waves that determine

[193] These results and an excellent discussion of the entire problem are in S. H. Schneider and R. Dennert, "Climatic barriers to long-term energy growth".

FIGURE 11-18

many climatic features long before global average warming becomes significant. [194] Computer models available in the mid-1970s were not sophisticated enough to represent the consequences of scattered human heat sources realistically. It seems likely on a variety of grounds, however, that another one or two doublings in energy consumption would place several of the world's most industrialized regions at a heat-source level capable of influencing climate over millions to tens of millions of square kilometers.

Agriculture and desertification. The earliest significant human influence on climate was undoubtedly that of vegetation changes brought about by human use of fire, deforestation, cultivation, and grazing. Subsequently, changes brought about by irrigation projects joined this category of climatic impacts associated with the provision of food and fiber. The scale of some of the modifications is suggested by the figures in Table 11-5, which represent significant changes both in energy balance and in water budget. (Note, for example, that an albedo increase of 0.02 over 10 percent of the continental land area produces a reduction of 51 million megawatts in the rate at which solar energy is absorbed at Earth's surface; this is about 6 *times* the rate of commercial energy use in 1975.)

As far as is known, the actual changes in climate associated with such surface alterations have been mainly regional, rather than global. (Neither measurements nor models have been good enough to be sure.) One reason for this may be that some human activities, such as irrigation of and lands, actually decrease albedo, which compensates to some degree for man-made increases in the albedo elsewhere.

Regional changes can themselves be devastating. There has been particular interest in possible climatological explanations of the prolonged drought of the late 1960s and early 1970s in sub-Saharan Africa, mentioned earlier. One observer has suggested that the drought could have been brought on, or at least aggravated by, the following chain of events: overgrazing bared high-albedo soils, a resulting drop in the absorption of solar energy at the surface reduced the heating of near-surface air, and the reduction of updrafts resulting from that phenomenon inhibited cloud formation and rainfall, producing drought. [195] (The increased albedo that can result from overgrazing is apparent in the satellite photo in Figure 11-19). A superficially similar plant-cover-albedo-rainfall feedback mechanism has been described by J. Charney, P. Stone, and W. Quirk; it seems more consistent than the first model with the large area of the effect observed in the Sahel, and its plausibility has been confirmed by incorporating the mechanism into a computer model of the global atmosphere that can account for interaction of the Sahel with other regions. [196]

Oil and ice. Oil slicks on the ocean surface change the albedo, the roughness (hence the energy transfer from surface to atmosphere), and the evaporation rate. Data on the sizes of oil slicks and their persistence is not as yet adequate to determine whether they influence meteorological conditions in more than a temporary and highly local fashion. [197]

It has been suggested that spills associated with oil production and transportation activities in the Arctic could have serious climatic effects there, because of the following combination of circumstances: under Arctic

Table 11-5 Scale of Climate-Related Alterations Associated with Agriculture (around 1970)

Alteration	Magnitude
Conversion of forest to fields and grasslands	18 to 20% of area of continents (albedo changed from 0.12-0.18 to 0.20)
Subsequent conversion of fields and grasslands to desert)	5% of area of continents (albedo changed from 0.20 to 0.28

Alteration	Magnitude
Area under irrigation	1.5% of area of continents
Reduction of continental runoff by irrigation	5%
Increase in continental evaporation due to irrigation	2%
Increase in evaporation from irrigated areas	100 to 1000%
Area covered by artificial reservoirs	0.2% of area of continents

conditions, biological degradation of spilled oil is very slow; the dynamics of the Arctic pack ice provides several mechanisms by which the oil can be spread over very large areas and then find its way to the surface of the ice, drastically reducing the albedo. The climate of the entire Northern Hemisphere is very sensitive to the heat balance in the Arctic. [198] Changes in albedo are particularly important there because of the very large amount of sunlight received in the polar summer (see Chapter 2) and the associated possibility of its completely melting the sea ice. Whether the ice would reform, once melted, is not known; dramatic changes in climate could be expected if it did not. [199] Whether oil spills really could cover enough area to raise this possibility is controversial: critics of the hypothesis claim that a 2-million-barrel spill could not cover more than 100 square kilometers of ice, compared to the 10 million square kilometers maximum extent of the sea ice; proponents say the coverage of such a spill could range from 240 to 800,000 square kilometers. [200]

Another possible threat to Arctic sea ice is a Soviet scheme for diverting major rivers now flowing into the Arctic Ocean. The project, underway in the mid-1970s, is expected to shift the flow southward for the purpose of irrigating parts of the Soviet Union previously too arid for cultivation; the residue is to flow into the Caspian Sea. The loss of the substantial freshwater flow of those rivers into the Arctic Ocean can be expected to increase the salinity of the surface layer, making it more difficult to freeze and possibly significantly reducing the area covered by sea ice. [201]

Modifying the Troposphere

The activities of civilization certainly have modified Earth's surface significantly, and they appear to be modifying the stratosphere. What of the troposphere, where most of the mass of the atmosphere resides and most of the motion that "produces" climate takes place? Aside from the influences already mentioned, civilization's direct impact on the troposphere is mainly of three kinds: an increase in the concentration of carbon dioxide, which is worldwide and uniformly distributed; an increase in the concentration of particles in the atmosphere over large regions (but little if any increase in other regions); and the production of high-altitude clouds initiated as jet aircraft contrails at the tropopause. The principal impact of all these phenomena occurs through the interaction of the contaminants with incoming solar radiation and outgoing terrestrial radiation.

Carbon dioxide. Combustion of fossil fuels at the 1975 rate would add carbon dioxide to the atmosphere at a rate sufficient to increase the atmospheric concentration of this gas by about 3 parts per million per year if it all remained in the atmosphere (see Chapter 3). In fact,

[198] W. J. Campbell and S. Martin, *Oil and ice in the Arctic Ocean: Possible large-scale interactions*. See also Chapter 2 for an expanded discussion of the sensitivity of hemispheric climate to Arctic conditions, and W. W. Kellogg, *Climatic feedback mechanisms involving the polar regions*.

[201] W. W. Kellogg and S. H. Schneider, *Climate stabilization: For better or for worse*.

however, it appears that only about 50 percent of the carbon dioxide that has been produced since heavy reliance on fossil fuels began toward the end of the nineteenth century has remained in the atmosphere, and that a similar fraction of what is now being injected is remaining there. [202] The remainder of the carbon dioxide presumably is being absorbed in the mixed layer of the oceans and, conceivably, part of it is appearing as an increase in terrestrial and oceanic biomass.

The part that remains in the atmosphere is of considerable climatic significance because of the crucial role played by carbon dioxide in Earth's energy balance through its greenhouse effect (Chapter 2). The atmospheric concentration of carbon dioxide increased by more than 10 percent (from about 290 ppm to 320 ppm) between 1880 and 1975, a finding supported by a number of

independent measurements. [203] If all other factors had been constant, the enhanced greenhouse effect associated with this increase could have increased the average global surface temperature about 0.3° C. [204] If the use of fossil fuels continues to grow at 3 to 4 percent per year, available models suggest an atmospheric concentration of carbon dioxide of between 365 and 385 parts per million in the year 2000 and, all other factors being constant, a corresponding temperature increase between 1975 and 2000 of 0.3° to 0.6° C. [205]

Significantly, moreover, Earth's climatic machinery is such that the effect of warming due to carbon dioxide is expected to be several times as great near the poles as on the average. [206] This means that a 0.5° C global average warming could cause significant changes in atmospheric circulation, extensive melting of sea ice, and perhaps the initiation of melting from the Greenland and Antarctic ice sheets with a concomitant increase in sea level.

Some complications must be mentioned, however. First, many factors other than fossil-fuel combustion are capable in principle of influencing the atmospheric concentration of carbon dioxide. They include, among others, the rate of uptake of carbon dioxide in ocean surface layers and the size of the planetary biomass. Some of these factors have been taken into account in the models used to arrive at the projections of future carbon-dioxide concentrations quoted above, but it is possible that important effects have either been left out or incorrectly modeled. This means the carbon-dioxide concentration could grow more rapidly than the models predict, or more slowly. Second, the warming associated with an increase in carbon dioxide could bring feedback loops into play that would either accelerate the warming trend (positive feedback) or slow it (negative feedback). An example of the former would be increased oceansurface temperatures driving more carbon dioxide out of solution and into the atmosphere; an example of the latter would be increased evaporation (because of the warmer surface temperature) producing increased cloud cover, which would cool the surface. Third, other, largely independent modifications of the troposphere are taking place that could further complicate the response to rising carbon-dioxide concentrations (chief among them are particles and aircraft contrails), as well as the other natural and human influences on climate discussed earlier in this chapter and in Chapter 2.

Particles and contrails. Particles in the atmosphere are of many sizes and compositions, corresponding to the diversity of their origins: smoke from forest fires, agricultural burning, and the combustion of fossil fuels; solid and liquid particles that began as gaseous emissions from combustion and natural processes; sea salt; dust from volcanic explosions and from agricultural activity. (The term aerosol is often used interchangeably with particles in the literature of climate, although technically aerosol refers to particles of less than 1 micron in diameter together with the gas in which they are suspended.) The exact magnitudes of the various sources of particles are in most cases uncertain, by significant amounts. A tabulation of estimates collected by the Study of Man's Impact on Climate [207] in 1971 appears in Table 11-6. The fraction of the total that is man-made probably falls somewhere between 10 percent and 30 percent.

TABLE 11-6 Particles Less Than 20 Microns in Radius Emitted into or Formed in the Atmosphere

Particles	Amount emitted into or formed in atmosphere (Million MT)
ANTHROPOGENIC PARTICLES	
Direct emissions of particles	10-90
Particles formed from SO_2 emissions	130-200
Particles formed from NO_x emissions	30-35
Particles formed from hydrocarbon emissions	15-90
NATURAL PARTICLES	
Volcanic debris	25-150
Sea salt	300
Particles formed from H_2S emissions	130-200
Particles formed from NH_3 emissions	80-270
Particles formed from NO_x emissions	60-430
Particles formed from hydrocarbon emissions	75-200
PARTICLES OF MIXED ORIGINS	
Soil and rock debris	100-500
Forest fires and slash burning	3-150
Rounded Totals	1000-2600

Even if the fraction were more accurately known, its meaning would be difficult to ascertain. Unlike carbon dioxide, particles generally do not become uniformly mixed in the atmosphere; their life expectancy before falling out is too short. Therefore, the concentration of particles in the atmosphere tends to be high for some distance downwind of the major sources and low elsewhere. [208] The smallest particles remain in the atmosphere longest and therefore have the biggest effects; this means that sources of small particles, whose contribution to emissions may not be very large by weight, make a disproportionate contribution in terms of climatic impact.

There is no doubt that major volcanic eruptions, when they occur, are the single greatest source of atmospheric particles; such eruptions put a considerable quantity of debris into the stratosphere, where it remains long enough to spread over an entire hemisphere. Climatic records indicate that uncommonly cold years have followed some of the major volcanic eruptions of the past 200 years, presumably because the particles have screened out some sunlight. [209]

It has been widely surmised that the growing influence of civilization's particle production between volcanic eruptions has had a similar cooling effect, and, indeed, that this might be responsible for the apparent worldwide cooling trend observed between 1940 and 1965. [210] (A widespread conjecture has been that an apparent global warming between 1900 and 1940 was caused by the buildup of carbon dioxide from the combustion of fossil fuels, after which the cooling effect of particles became dominant and reversed the trend.)

Considerable doubt has been cast on this point of view by growing understanding of the complexity of the interaction of atmospheric particles with radiation, and by a lack of evidence that increases in particles have been more than regional in extent. With respect to the first point, it is now known that under some circumstances particles can have a net heating effect rather than a cooling effect; what happens depends on the size and composition of the particles, on their altitude, on the reflectivity of underlying clouds, and on the reflectivity of Earth's surface. [211] Concerning the areal extent of increases in particles from human activities, coverage has been much greater in the Northern Hemisphere than in the Southern; the climatic influence of this may have been appreciable, but its effect is surely more complicated than a uniform cooling.

As noted in Chapter 2, particles play another important role in climatic processes by serving as condensation centers for the formation of water droplets or ice crystals when the relative humidity exceeds 100 percent. Although there is virtually always a surplus of atmospheric particles that could serve as condensation nuclei if the relative humidity were very high, the actual dynamics of cloud formation is governed by that class of particles whose properties permit condensation when the relative humidity first barely exceeds 100 percent. That class of particles, called *cloud nuclei*, is defined as particles that are active condensation centers below 101 percent relative humidity. [212] Particles that have the property of initiating freezing in a droplet that contains them are

[212] SMIC, *Inadvertent*, pp. 220-223.

called *ice nuclei*. Under many circumstances, an increase in the atmospheric concentration of cloud nuclei can increase cloud cover but decrease rainfall, because more but smaller droplets are formed, and small droplets do not fall as readily as large ones. Man-made particles can also

have the effects of increasing rainfall and decreasing cloud cover -- this is what is done intentionally in cloudseeding programs to stimulate rainfall -- but those phenomena seem to be rarer than those with the opposite effect (decreasing rainfall, increasing cloud cover). Present data are inadequate to discern any long-term global trend in cloud cover that might be occurring because of particle pollution. There is some local evidence, however, of an increase in the albedo of clouds to which extra cloud nuclei have been added by human activities. [213]

In the upper troposphere and lower stratosphere, where subsonic jet airliners cruise, the natural humidity tends to be very low. There, the availability of water vapor, more than the properties of condensation nuclei, governs the formation of the cirrus clouds that can exist at those altitudes. The white contrails often visible from the ground behind high-flying jet planes are ice clouds formed from the water vapor supplied by the aircraft's exhausts. Water vapor added to the atmosphere near the tropopause could be sufficient to trigger increased high cloud cover over very large areas of the globe by the 1980s; since 1965 an increase in high cloud cover over the United States, which *might* be due to aircraft operations, has been measured. [214] The effect of high cloudiness in areas where there is no low cloud cover below is to cool the surface during the day and to warm it somewhat at night, the latter produced by an enhanced greenhouse effect. Which is the stronger effect depends on the detailed properties of the clouds, which vary widely. [215]

What's Happening, and Why Does It Matter?

A principal message of the foregoing discussion of civilization and climate is that climate is very complicated and imperfectly understood, as are the human interventions in various aspects of the climatic machinery. What can be stated with assurance is that human modification of Earth's vegetation has had significant (if gradual) effects on the climates of large regions, that densely populated urban centers in industrialized countries have had quite extreme climatic effects extending over areas on the order of 10,000 square kilometers each, and that continuation of exponential growth in energy use would *eventually* lead to intolerable global climatic change from the effects of heat dissipation alone. With almost as much certainty we can say that the buildup of atmospheric carbon dioxide in the past seventy-five years has been due mainly to the combustion of fossil fuels, and that one effect of that buildup *would* have been (in the absence of other changing factors) a modest increase in average global surface temperature. Finally, we can say that the magnitudes of other human interventions in processes that influence climate -- such as catalyzing the destruction of atmospheric ozone, alteration of the coverage of Arctic sea ice, modification of the atmosphericparticulate load over large regions, and augmentation of high cirrus clouds with water vapor from jet exhausts -already are or soon will be great enough to raise the *possibility* of significant disruption of climate in ways whose details still cannot be predicted with any confidence.

Role of civilization in observed climatic changes. The relative responsibility of man-made and natural processes for the variations in climate that actually have taken place in this century is controversial (see Box 11-5). The case for the importance of human influences to date -- particularly the combination of carbon dioxide and particles -- has been presented urgently and in many forums by meteorologist Reid Bryson. [216] He has put forward the hypothesis that the persistent failure of the summer monsoons in sub-Saharan Africa in the late 1960s and early

1970s, which produced severe drought in that region, could have been caused by a change in circulation patterns understandable as the combined effect of carbon dioxide and particles. Basically, his argument is that man-made particles cool the middle to high latitudes more than the equatorial latitudes, increasing the strength of the circumpolar vortex that is

BOX 11-5 Some Anomalies in Regional and Global Climates in the 1960s and 1970s

Climate has always been changing, and the details of the changes have always been to a great extent unpredictable. Whether any given shortterm change represents a turning point in a long-term pattern rather than a mere fluctuation is impossible to say at the time the change is experienced. Climatologists define normal climate as the average of a recent thirty-year period--in the early to mid-1970s the period in use was 1930 to 1960. Departures from the norm can take the form of *trends* in the average value of such indicators as temperature or rainfall, or else the *variability* of those quantities from year to year can change whether or not the several-year average is changing.

The historical evidence makes it quite clear that the world's climate from 1930 to 1960-today's defined norm -- was representative of one of the warmer periods in the last hundred millennia (see Chapter 2). It is reasonably clear that a cooling trend began to set in between 1940 and 1945, at least in the Northern Hemisphere, although the data for the Southern Hemisphere are scantier and not indicative of cooling. Many observers have speculated that the cooling could be the beginning of a long and persistent trend in that direction -- that is, an inevitable departure from an abnormally warm period in climatic history.

There would be enormous uncertainty in arguing that the middle of the twentieth century will prove to be such a turning point, however, even without the possibility that civilization itself may be influencing the climatic machinery to be other than it would have been by itself. At the same time, the evidence is sufficient to show that the least that has been happening in the 1960s and 1970s is a considerable increase in the variability of climate compared to the earlier part of the century.

There is evidence, for example, that the growing seasons in Canada, Iceland, and England have shortened by a few weeks for a number of years in this period and that rainfall has decreased significantly in southern England. The winter of 1962/ 1963 was one of record-breaking cold throughout Europe. The year 1972 was characterized by unusual floods in the midwestern United States, warming of the coastal waters off Peru, an extension of a drought that had commenced a few years earlier in sub-Saharan Africa, delayed onset of the monsoon in India, and a severe drought in the USSR. In 1974 the United States and Canada experienced excessive spring rainfall, intense drought in July, and early fall frosts, while Brazil suffered the worst floods in history. [*] The USSR had a wheat-crop failure in 1975 because of drought. In 1976, western Europe suffered unprecedented heat and drought during the summer months. The winter of 1976-1977 was one of the driest on record in the western United States and one of the snowiest in the eastern U.S. Regardless of whether all these events are parts of a consistent trend and whether human activities have yet influenced these phenomena, the very fact of increased climatic variability is bad news in a world with decreasing leeway for adjusting to surprises.

driven by that gradient (Chapter 2). At the same time, says Bryson, the effect of carbon dioxide in changing the vertical temperature profile of the lower atmosphere is more important than its overall warming effect, and the weakening in subtropical circulation patterns induced by this altered vertical temperature profile reinforces the effect of the strengthening of the circumpolar vortex. The net result may have been to push the summer position of the intertropical convergence southward, keeping the monsoons and their rainfall out of the Sahel. Various aspects of Bryson's view have been disputed.

Mitchell argues, for example, that until now natural sources (particularly volcanoes) have contributed more particles than have human activities. [217] Schneider and Mass have argued that much of the global climate variation of the past 400 years possibly could be explained by variations in solar output (correlated with sunspot cycles) together with changes in the amount of volcanic dust in the atmosphere. [218] Some others appear

[*] For a good review of these events, see Schneider and Mesirow, *The Genesis strategy*.
[217] Mitchell, *A reassessment*.
[218] S. H. Schneider and C. Mass, *Volcanic dusts, sunspots, and temperature trends: Climatic theories in search of verification*.

to believe that our knowledge of climate is still so inadequate that any speculation about the cause of a particular change is premature. Regardless of the extent to which Bryson's view and other such hypotheses prove right or wrong in detail, however, those kinds of analysis have served a useful function in calling attention to the idea that alteration of circulation patterns is a more significant and more imminent form of climatic change than changes in average surface temperature.

The only real certainty about climate change is that *it will happen*. Even without the inadvertent influences of civilization, the natural forces that have produced rather drastic variations in climate throughout Earth's history will continue to produce them. In the long term, the expected

natural trend in the absence of human influences is a cooling from the unusually warm conditions that have prevailed over the past hundred years. [218a] The likelihood of cooling on a time scale of hundreds to thousands of years, however, does not rule out the possibility of shorter periods of warming superimposed on the long-term trend; if the correlation between sunspot cycles and climate proves out, this combined with accumulating CO_2 could produce such a short-term warming beginning around 1980. [219]

If there is any consensus on the likely overall direction of human influences on climate in the future, it is a shaky one to the effect that the dominant influence is or soon will be in the direction of global warming. The bases for this view are that the increase in carbon dioxide from human activities is global and consistently produces a warming effect, whereas the man-made increase in particles is regional and produces cooling *or* warming, depending on circumstances. That changes in patterns of circulation and the accompanying changes in precipitation and extremes of temperature are more important than changes in mean global temperature cannot be emphasized enough, however. This is why there can be scant consolation in the idea that a man-made warming trend might cancel out a natural cooling trend. Since the different factors producing the two trends do so by influencing different parts of Earth's complicated climatic machinery, it is most unlikely that the associated effects on circulation patterns would cancel each other.

Consequences of climatic change. If climate change is a historical fact and a future inevitability, why worry? The argument is often put forward that people have survived climate change in the past and will continue to do so. Moreover, the argument goes on, if civilization adds its own influences to natural climatic trends, how do we know the result won't be an improvement?

The response to this has several parts. First, to talk merely of survival as a species is to evade the issue of the degree of social disruption and human suffering that have attended regional climatic change in recent history and, presumably, at times in the more distant past. That the drought-induced famine in the Sahel in the early 1970s did not threaten to extinguish the human race is no consolation to the thousands who died. The problems besetting prehistoric human populations in the Northern Hemisphere during the probably rapid onset of the latest ice age can only be imagined, but they must have been severe.

Today, moreover, the absolute magnitude of the human misery that could be caused by climate change is much larger than it ever was because the human populations in virtually all regions of the world are much larger than they were before. Far more people would be affected by any given regional climatic change, and there is not likely to be any room in adjacent regions into which they could flee.

The part of the ecosphere most sensitive to climatic change -- that is, the element most easily disrupted to the point of directly influencing human well-being -- is agriculture. [220] Farmers know very well that a year's crop can be ruined by rain that comes too early or too late, or in too great quantity or too little, by too much hot weather or too much cold, by early frosts, and by other vagaries of weather. And a small change in average conditions can change the extremes enough (for example) to change the

[218a]This conclusion follows not only from casual examination of the place of today's conditions in the pattern of climatic variation over the past million years (see Chapter 2), but it has gained recent support from a very thorough study of the effect on climate of variations in Earth's orbit taking place over time periods of tens of thousands of years (J. D. Hays, J. Imbrie , and N. J. Shackleton, *Variations in Earth's orbit: Pacemaker of the ice ages*).

[219]Schneider and Mass, *Volcanic dusts*.

[220]S. B. Idso, in *Man's impact*, Matthews, Kellogg, and Robinson, eds., pp. 184-191.

length of the growing season substantially. Not surprisingly, then, there is a strong and well-documented connection between weather and agricultural production nationally and worldwide--"good" weather means high yields; "bad" weather means low yields. Furthermore, increased *variability* in weather can be as disruptive of agriculture as changes in mean conditions. [221]

This phenomenon is the reason that *no* rapid change in climate is likely to be an improvement; the crops grown in a given region generally are quite closely adapted to the typical weather pattern -- the climate -- in that region. Therefore, any significant change tends to be, from the standpoint of growing a particular crop, a change from good weather to bad. Farming practices -- time of planting, in particular -- are also based on expected weather patterns. Naturally, patterns of agriculture could be modified to follow at least some kinds of climatic change, if the change were gradual enough. Artificially induced climatic change might be quite rapid, however, as indeed some natural changes apparently have been in the past. As discussed in Chapter 7, there is no leeway in the world food situation to absorb a significant climate-induced drop in production over broad areas of the world. Whatever adjustments in crop characteristics and cultivation patterns might *eventually* be made in response to rapid climate change would come too late to save hundreds of millions from famine.

Another, somewhat more speculative respect in which climate change could lead to great increases in human misery is by altering the abundance and the geographical distribution of various disease-producing organisms. As is the case with crops, the degree to which such organisms and the other organisms that transport them (vectors) thrive is governed by such environmental conditions as temperature and moisture, in terms of both averages and extremes. Changes in climatic patterns therefore might give certain of those organisms access to human populations that have no prior evolutionary experience with them and hence little or no resistance to them. Alternatively, such changes might remove checks on the abundance of organisms preexisting in an area, to the extent that a previously minor hazard becomes a plague. (This is true of pathogens that attack crops and trees, as well as those that attack people.) [222]

It is obvious, of course, that sustained climatic change either in the form of a new glaciation or a prolonged warming that involved substantial melting of the Greenland and Antarctic ice sheets would change the pattern of human settlement as well as that of agriculture. The melting of half the volume of present ice sheets would raise sea level by about 40 meters, enough to flood most coastal cities and cover many fertile coastal plains. Such extensive melting would require enormous amounts of energy, however, and so could not occur overnight. If climate changed so drastically that an additional 5 percent of all the solar energy now reaching Earth's surface were

absorbed in the melting of ice (compared to the fraction of a percent presently absorbed in summer melting of ice that is restored in winter), sea level would rise about 1.1 meters per year. [223] A climate change great enough to produce this result would damage world agriculture so severely that the effect of the initial change in sea level would hardly be noticed by comparison.

Intentional Modification of Weather and Climate

The idea of influencing the weather intentionally dates back to the rain dances and related rituals of many nontechnological civilizations. Modifying the weather by technological means, however, had its real beginnings in 1946, when it was demonstrated that seeding clouds with dry ice or silver iodide could produce precipitation when none would have occurred naturally. Thirty years later, rainmaking was rather widely practiced in some parts of the world, but many details of its effectiveness and side effects remained controversial. Rainmaking works under some meteorological conditions but not under others; sometimes the attempt may actually pro-

[221] For more extensive discussion and more reviews of recent statistics, see Chapter 7 and Schneider and Mesirow, *The genesis strategy*.

[222] See J. M. May, Influence of environmental transformation in changing the map of disease, in *The careless technology*, Farvar and Milton, eds.; G. H. Hepting, Climate and forest diseases, in *Man's impact*, Matthews, Kellogg, and Robinson, eds., pp. 203-226.

[223] This figure is readily obtained from the following data: heat of melting of ice, 330 megajoules per cubic meter of water produced; area of oceans, 360×10^{12} square meters; solar energy reaching Earth's surface, 2.7×10^{18} megajoules per year.

duce less precipitation than would have occurred naturally. How far downwind of the seeding activity the effects persist is not known, and the genuine possibility of decreasing needed rainfall on neighboring regions (including neighboring nations) poses serious political problems. [224]

Seeding has been used not only to produce rain, but also, under varying circumstances, to dissipate cold fog (by initiating formation of ice crystals that fall out), to suppress hail (by fostering formation of many small particles rather than fewer large ones), and to steer hurricanes and/or weaken the winds associated with them. These measures, too, have the potential for inadvertent side effects and for transferring bad weather to one's neighbors. Indeed, Honduras blamed its disastrous hurricane (Fifi) of 1974 on just such activity by the United States, although there is no evidence to support the claim and the United States weather bureau denied it.

The practice of altering hurricanes contains the remarkable possibility that intentional weather modification on one scale will lead to unintentional climate modification on another. This is so because those tropical storms play a crucial role in the global climatic balance by transporting energy from the warm tropics into the cooler middle latitudes. Systematic disruption of that function would unquestionably produce significant alterations of climate over large regions, in forms not now predictable in detail.

Intentionally modifying not merely the local phenomena that make up the weather, but also the climate over large regions, has been discussed for years. We might hope that the rather primitive state of knowledge concerning climatic machinery and how civilization may unintentionally be modifying it would discourage all groups from any deliberate intervention for a long time to come, but governments and other bodies have all too often shown themselves incapable of sensible restraint. Among the schemes that have been mentioned are: sprinkling soot on the Arctic sea ice to melt it, causing warmer but probably more snowy winters in the Arctic region; damming the Bering Strait, another way of causing the Arctic sea ice to melt, damming the Gulf Stream between Florida and Cuba; and creating a layer of stratospheric dust to counteract global warming due to carbon-dioxide buildup. [225] In all these cases, present knowledge is inadequate to show that the unintended consequences would not exceed the intended ones.

Naturally, the possibility of using weather modification as a weapon has not escaped the notice of military planners. The only known instance of actual use of such techniques, as of 1977, was the use of cloud seeding by the United States in Vietnam between 1967 and 1972. The aim of those operations was to inhibit the movement of troops and supplies along the Ho Chi Minh Trail. The actual physical effect was probably minimal: 5 or 6 centimeters may have been added to the typical monsoon rainfall of about 50 cm. [226] The international political impact of the precedent of American use of weather as a weapon may be much greater.

As understanding of climatic processes increases, the possibilities of misusing the new knowledge for weaponry become more awesome. The possibility of using chemicals to poke holes deliberately in another nation's ozone shield is now obvious enough, and intentional manipulation of storms and droughts does not seem entirely farfetched. Geophysicist Gordon MacDonald has emphasized the possibility that environmental warfare using climate modification could be carried out covertly over a period of years without the victims' being aware of the cause of their misfortunes. [227]

The potential for destruction, both intentional and inadvertent, associated with climatic warfare is second only to that of biological and nuclear war (and even this ranking may eventually prove to be questionable). It is therefore of the greatest importance to outlaw the use of weather- and climate-modification weapons by international agreement, notwithstanding the obvious difficulties of monitoring and enforcement. The Soviet Union and the United States submitted a joint proposal for a

[225] See Kellogg and Schneider, *Climate stabilization*.

[226] The Vietnam operations and other important elements of military weather modification are described in G. J. F. MacDonald, "Weather as a weapon", *Technology Review*, vol. 78, no. 1 (Oct / Nov 1975), pp. 57-63.

[227] Ibid.

pact prohibiting environmental warfare to the Geneva disarmament talks in August 1975. The pact would rule out "military or other hostile use of environmental modification techniques having widespread, long-lasting or severe effects as the means of destruction, damage, or injury to another state." [228] This wording would preclude not only modification of weather and climate for military purposes, but also the intentional production of earthquakes, tidal waves, and ecological imbalances of various kinds.

THERMONUCLEAR WARFARE

Much has been written, especially by military theoretician Herman Kahn, on the effects of thermonuclear warfare, the possibilities of limited thermonuclear warfare, and so on. [229] Since modern societies seem bent on continuing to prepare for such conflicts, we have little sympathy for those of Kahn's critics who feel that it is immoral to try to analyze the possible results. It would be pleasant (but probably incorrect) to assume that if everyone were aware of the terrible magnitude of the devastation that could result from a nuclear war, the stockpiles of fission and fusion weapons would soon be dismantled. This does not mean that Kahn's analysis is sound -- quite the contrary. It has the major flaw of grossly underrating the possible environmental consequences of those projected wars. In addition to the instantaneous slaughter of millions of people and the demolition of property, the effects of any large thermonuclear exchange would inevitably constitute an enormous ecological and genetic disaster -- especially for a world already on the edge of nutritional and environmental catastrophe.

Consider the effects that even a rather limited nuclear exchange among the United States, USSR, China, and various European powers would have on the world food supply. Suddenly, international trade would be greatly reduced, and the developed world would be in no position to supply either food or technological aid to the less developed. No more high-yield seed, no more fertilizers, no more grain shipments, no more tractors, no more pumps and well-drilling equipment, trucks, other manufactured products or machines would be delivered. Similarly, the LDCs would not be able to send DCs minerals, petroleum, and food products. The world could be pitched into chaos and massive famine almost immediately, even if most countries were themselves untouched by the nuclear explosions.

But of course no country would be left unscathed. All over the world radiation levels would rise, possibly preventing cultivation of crops in many areas. Blast effects and huge fires burning in the Northern Hemisphere would send large amounts of debris into the atmosphere, conceivably dwarfing the volcanic and pollution effects previously discussed. [230] The entire climate of the Earth could be altered, especially since large holes would probably be punched in the ozone layer. In many areas, where the supply of combustible materials was sufficient, huge fire storms would be generated, some of them covering many hundreds of square kilometers in heavily forested or metropolitan areas.

Something is known about such storms from experience during World War II. On the night of July 27, 1943, Lancaster and Halifax heavy bombers of the British Royal Air Force dropped 2200 metric tons of incendiary and high-explosive bombs on the city of Hamburg. Thousands of individual fires coalesced into a fire storm covering about 15 square kilometers. Flames reached 4500 meters into the atmosphere, and smoke and gases rose to 12,000 meters. Winds, created by

huge updrafts and blowing in toward the center of the fire, reached a velocity of more than 240 kilometers per hour. The temperature in the fire exceeded 787° C, high enough to melt aluminum and lead. Air in underground shelters was heated to a point where, when they were opened and oxygen was admitted, flammable materials and even corpses burst into flame. The shelters had to cool for *ten days to two weeks* before rescuers could enter.

Anyone interested in further details of what a small fire storm is like is referred to Martin Caidin's excellent book, *The night Hamburg died*. [231] From his account, we

[229] Herman Kahn, *On thermonuclear war*; and *On escalation*.
[230] The extent of fires is a matter of some controversy--see W. S. Osburn, Jr. , *Forecasting long-range ecological recovery from nuclear attack*.
[231] Ballantine, New York, 1960. For a literary view, see Kurt Von negut 's *Slaughterhouse five*, which describes the results of a similar raid on Dresden Dell, New York, 1971).

can imagine the ecological consequences of generating numerous fire storms and burning off a substantial portion of the Northern Hemisphere. In areas where conditions led to the development of fire storms, the removal of all vegetation would not be the only effect; the soil might be partly or completely sterilized, as well. There would be few plant communities nearby to donate the seeds for rapid repopulation, and rains would wash away the topsoil. Picture what now happens on defoliated California hills during the winter rains, and then imagine the vast loads of silt and radioactive debris being washed from immense bare areas of northern continents into offshore waters, the site of most of the ocean's productivity. Consider the fate of aquatic life, which is especially sensitive to the turbidity of the water, and think of the many offshore oil wells and supertankers that would be destroyed by blast in the vicinity of large cities and left to pour their loads of crude oil into the ocean. Think of the runoff of solvents, fuels, and other chemicals from ruptured storage tanks and pipelines. And radioactivity from nuclear reactors, fuel reprocessing plants, and other nuclear-power facilities would be added to that of the bombs themselves.

Ecosystems would be assaulted as they are assaulted in peacetime (as we have seen, radiation stresses do not differ greatly from others), but the scale of the assault and its rapidity would be unprecedented. Recovery would inevitably be much slower than from other kinds of ecocatastrophes. [232]

The human survivors of any large-scale thermonuclear war would face a severely devastated environment. If a full-scale war were waged in which a substantial portion of United States and Soviet weapons were detonated, most of the survivors would be in the Southern Hemisphere. They would lack many of the tools needed to maintain a modern civilization, since much technology would be irretrievably lost. If the technological structure of society were destroyed, it would be almost impossible for survivors to rebuild it because of resource depletion. Most high-grade ores and rich and accessible fossil-fuel deposits have long since been used up. Technology itself is necessary for access to what remains. Only if enough scrap metals and stored fuel

remained available would there be a hope of reconstruction, which would have to begin promptly before those stocks rusted, drained away, or were lost in other ways. Even more serious, banks of plant genetic material would certainly be destroyed or lost through lack of care, making the regeneration of high-yield agriculture difficult or impossible. From what is known of past large disasters, it seems unlikely that survivors, without outside assistance, would be able psychologically to start rapid reconstruction. [233]

If there were extensive use of nuclear weapons in both hemispheres, or if chemical or biological weapons were used simultaneously, the survivors would probably consist of scattered, isolated groups. Such groups would face genetic problems, since each would possess only a small part of humanity's genetic variability and would be subject to a further loss of variability through inbreeding. Studies of human populations have shown that inbreeding increases infant mortality. In addition, it appears that prenatal damage increases linearly with the degree of inbreeding. [234] In such a situation it is problematical whether culturally and genetically deprived groups of survivors could persist in the face of much harsher environmental conditions than they had faced previously. In short, it would not be necessary to kill every individual with blast, fire, radiation, nerve gas, and pathogens in order to force *Homo sapiens* into extinction.

ECOLOGICAL ACCOUNTING

Many existing and potential forms of ecological disruption have been described in this chapter, sometimes in rather technical detail. It may be helpful at this point to summarize the relevance of these considerations to human welfare. In other words, just what could an ecological catastrophe mean for human beings?

The various ways in which the biosphere supports human life were outlined at the beginning of the chapter.

---

[232] E. P. Odum, Summary, in *Ecological effects of nuclear war*, G. M. Woodwell , ed., pp. 69-72. See also NAS, *Long-term*, which is incomplete and has poorly-thought-through conclusions but contains useful data and bibliographies.

[233] There is a fascinating literature on reactions to and recovery from catastrophes. See A. H. Barton, *Communities in disaster: A sociological analysis of collective stress situations*, especially the last chapter.

[234] L. L. Cavalli-Sforza and W. F. Bodmer, *The genetics of human populations*, W. H. Freeman and Company, San Francisco, 1971.

The loss of one or more of those vital services would kill or seriously impair the health of a significant fraction of the human population. Such a loss could result from any large-scale ecological breakdown, but there are relatively few forms that its human consequences can take. Probably the most likely would be a widespread shortage of food. Such a shortage could result from the disruption of oceanic food webs, from progressive loss of soil fertility or of soil itself, from outbreaks of crop pests brought about by misuse of pesticides, from crop failures initiated

by changed climatic conditions or plant diseases attacking vast monocultures, or from a combination of such factors.

Perhaps the second most likely event would be a deterioration of public health resulting from an accumulation of toxic or disease-harboring substances at overloaded links in nutrient cycles (for instance, surface waters overloaded with organic matter or the accumulation of nitrites in groundwater and soil), and including the possibility of epidemic disease.

A third might be a dramatic rise in the incidence of birth defects and cancers, brought about by the individual or combined effects of the array of persistent mutagens and carcinogens that society continues to disperse in the biosphere.

The role of population size and distribution in generating ecological problems has been touched upon here already and is treated more systematically in Chapter 12. A point that should be obvious but that is often overlooked is that population factors can also govern the seriousness of a disruption, once one is underway. For example, it is largely because the growing population has stretched food production to its limits that there is little reserve against temporary crop failures caused by pests, plant disease, or weather variations. The sheer size and density of the human population in many parts of the world helps to make external aid almost impossible in time of local famine or other disaster. Epidemic diseases, on the other hand, can spread more readily through dense populations, especially when malnourishment has made resistance low.

Moreover, as a population grows, a larger portion of its people tend to live in hazardous locations. Biologists have long recognized that the size of a population relative to the area supporting it almost always influences the death rate when disaster strikes. As ecologists H. G. Andrewartha and L. C. Birch state in their classic book, *The distribution and abundance of animals*.

It is difficult to imagine an area so uniform that all the places where animals may live provide equal protection from the elements, and it is certain that the proportion of animals living in more favorable places would vary with the density of the population. A smaller number is likely to be better protected than a larger number in the same area. [235]

Human beings are no exception. For instance, since the famous 1906 earthquake, a growing proportion of the rapidly increasing population of the San Francisco Bay area has been housed on landfill, on sea cliffs, and even along the fault itself (Figure 11-20). Most of the buildings on landfill and other geologically unstable substrates have not been built to withstand the extraordinary shaking to which such structures are subjected in an earthquake. Geologist R. H. Jahns, discussing this situation, wrote, "The oft-used analogy of a block of Jello on a vibrating platter is grossly simplified but nonetheless reasonable, and assuredly a structure that in effect is built upon the Jello must be designed to accommodate greater dynamic stresses if it is to survive the shaking as effectively as a comparable structure built upon a platter." [236] When the next big earthquake occurs in that overpopulated area, a great many people are likely to die simply because they are living in geologically marginal locations.

On the Ganges delta of Bangladesh, a large, mostly destitute population lives exposed on flat lowland, despite the ever-present danger of climatic disaster for which the region is famous. They live on the delta because there is no room for them elsewhere in grossly overpopulated Bangladesh. In November 1970, some 300,000 people perished when a huge tidal wave driven by a cyclone swept over the delta. Most of the victims would not have died if their land had not been overpopulated. Because of the poverty and overcrowding, evacuation following the flood was impossible. And, because the region was already nutritionally marginal, people

[236]Geologic jeopardy.

FIGURE 11-20
Development near the San Andreas Fault on the San Francisco Peninsula. The broken white line shows the approximate location of the fault. A manifestation of excessive population density, lack of adequate zoning regulations, and the irresponsibility of developers in the location of homes and schools virtually astride major earthquake faults and on coastal bluffs subject to

periodic slides (*left foreground*). Note homes placed between areas where slides have already occurred. (Photo by William A. Garnett.)

were starving immediately after the disaster. This cataclysm was described as the greatest documented natural disaster in history. [237]

Governmental and other decision-makers, whose job it is to weigh the costs and benefits of alternative courses of action, have rarely given much weight to the considerations discussed in this chapter. In the past, the environmental consequences of human activities have usually not been linked in the minds of policy-makers to the specific kinds of actions (or lack of them) that caused the problems. As environmentalists now strive to bring such costs into society's balance sheets, they find themselves bearing a heavy burden of proof.

After all, say the defenders of the status quo, environmentalists cannot show exactly when or how an ecological disaster will take place, or how many human lives will be lost. Without solid evidence, how is one to act? This point of view is leading society to treat grave risks that are poorly understood as if they were no risks at all. In any balance sheet of costs and benefits, this is faulty accounting. One does not need to know the date of a future flood to avoid building residential developments on floodplains, or the exact magnitude of a possible earthquake to keep nuclear reactors away from major faults. If a risk entails the potential for major impact on human welfare and if actions that increase the risks are identifiable, then it is only prudent to avoid or restrain such actions as far as possible, even when knowledge concerning the risk is incomplete.

Ecological disruption clearly entails such risks, and it is time to shift the burden of proof. Where, for example, are the benefits of population growth that justify the ecological risks accompanying it? Despite social, economic, and political barriers to proper ecological accounting, it is urgent and imperative for human society to get the books in order.

Borthwick, P. W.; T. W. Duke; A. J. Wilson, Jr.; J. I. Lowe; J. M. Patrick, Jr. ; and J. C. Oberheu. 1973. "Accumulation and movement of Mirex in selected estuaries of South Carolina, 1969-71". *Pesticides Monitoring Journal*, vol. 7, pp. 6-26.
Bourne, W. R. P. 1976. Seabirds and pollution. In R. Johnston, ed., *Marine pollution*, pp. 403-502, Data on types of pollution and their effects in different areas and on different types of birds. Includes interesting accounts of individual pollution incidents.

Box, T. W.; R. F. Hadley; and M. G. Wolman, eds. 1974. *Rehabilitation potential of*

western coal lands. Ballinger, Cambridge, Mass. Comprehensive and up-to-date.
Brown, M. 1975. "An orange is an orange". *Environment*, vol. 17, July/August, pp. 6-11. Pesticide abuses in a campaign against cosmetic pests of California oranges, the citrus thrips.
Brown, W. L., Jr. 1961. "Mass insect control programs: Four case histories". *Psyche*, vol. 68, pp. 75-111. A distinguished entomologist and population biologist evaluates attempts to control the fire ant, the gypsy moth, the Mediterranean fruit fly, and the screwworm.
Bryson, R. A. 1973. "Drought in Sahelia: Who or what is to blame?" *The Ecologist*, vol. 3, (October), pp. 366-371. Popular summary of Bryson's theory of the meteorological factors contributing to the failure of the monsoons in the late 1960s and early 1970s.
-----. 1974. "A perspective on climatic change". *Science*, vol. 184, pp. 753-760 (May 17). Significant changes in climate can result from small changes in the governing variables. The role of man-made atmospheric particles and carbon dioxide is reviewed and found significant.
-----, and T. J. Murray. 1977. *Climates of hunger*. University of Wisconsin Press, Madison. An important overview of climatic change.
----- and W. M. Wendland. 1975. Climatic effects of atmospheric pollution. In *The changing global environment*, S. F. Singer, ed. Reidel, Dordrecht, Netherlands, pp. 139-147. Summarizes the case for believing man-made carbon dioxide and particles to be important factors in climate variations since 1940.
Budyko, M. I. 1974. *Climate and life*. Academic Press, New York. Outstanding text by one of the world's most respected figures in climatology.
Burgess, H. D., and N. W. Hussey, eds. 1971. *Microbial control of insects and miles*. Academic Press, New York. Comprehensive, technical. A wide range of subjects, including resistance, interactions between pathogens, propogation, and economics.
Burnett, Robin. 1971. "DDT residues: Distribution of concentrations in Emerita analoga (Stimpson) along coastal California". *Science*, vol. 174, pp. 606-608 (November 5). Shows a concentration much higher near the outfall of a DDT-manufacturing plant than in an agricultural runoff area.
Burns, N. M.; J.-M. Jaquet; A. L. W. Kemp; D. C. L. Lam; J. H. Leach; M. Munawar; T. J. Simons; P. G. Sly; R. L. Thomas; N. H. F. Watson ; and J. D. H. Williams. 1976. "Processes within Lake Erie". *Journal of the Fisheries Research Board of Canada*, vol. 33, pp. 639-643 (March). Summarizes an issue devoted entirely to the condition of Lake Erie.
Bush, G. L. 1975. Genetic variation in natural insect populations and its bearing on mass-rearing programmes. In *Controlling fruit flies by the sterile-insect technique*. International Atomic Energy Agency, Vienna, pp. 9-17, IAEA-PL-582/2. Describes large genetic changes due to domestication of the flies.
----- and R. W. Neck. 1976. "Ecological genetics of the screwworm fly", *Cochliomya hominivorax* (Diptera: Calliphoridae) and its bearing on the quality control of mass reared insects. Journal of Environmental Entomology, in press. Up-to-date report on genetic differences between mass-reared and wild strains, showing important differences in loci involved in producing enzymes critical to flight activity.
-----; R. W. Neck; and G. B. Kitto. 1976. "Screwworm eradication: Inadvertent selection for noncompetitive ecotypes during mass rearing". *Science*, vol. 193, pp. 491-493 (August 6). More on the problems of rearing sterile males to compete with wild ones.
Butler, P. A. 1969. The significance of DDT residues in estuarine fauna. In *Chemical*

fallout: Current research on persistent pesticides, W. M. Miller and G. G. Berg, eds, Charles C. Thomas, Springfield, Ill., pp. 205-218. Contains information on ability of oysters to concentrate DDT.
----- and P. T. Spruger. 1963. Pesticides: A new factor in coastal environments. In *Transactions of the twenty-eighth North American wildlife and natural resources conference*, pp. 378-390. Summary, with good bibliography of papers.
by erly, T. C. 1975. Nitrogen compounds used in crop production. In *The changing global environment*, S. F. Singer, ed. Reidel, Dordrecht, Netherlands, pp. 377-382. Reprint of 1970 analysis with short update.
Cade, T. J.; J. L. Lincer; C. M. White; D. G. Rosenau; and L. G. Swartz. 1971. "DDE residues and eggshell changes in Alaskan falcons and hawks". *Science*, vol. 172, pp. 955-957 (May 28). Shows a strong relationship between DDE content and eggshell-thinning.
Cairns, John Jr. 1974. "Indicator species vs. the concept of community structure as an index of pollution". *Water Resources Bulletin*, vol. 10, pp. 338-346. A general discussion.
-----, J. W. Hall, E. L. Morgan, R. E. Sparks, W. T. Waller, and G. F. Westlake . 1973. "The development of an automated biological monitoring system for water quality". Virginia Water Resources Research Center, Blacksburg, bulletin 51. Describes a system that continuously monitors breathing and swimming activity of fishes exposed to effluent.
Cairns, J. Jr.; G. R. Lanza; and B. C. Parker. 1972. "Pollution related structural and functional changes in aquatic communities with emphasis on freshwater algae and protozoa". *Proceedings of the Academy of Natural Sciences of Philadelphia*, vol. 124, pp. 79-127. A comprehensive review with a fine bibliography.
Cairns, J. Jr.; R. E. Sparks; and W. T. Waller. 1973. "The use of fish as sensors in industrial waste lines to prevent fish kills". *Hydrobiologia*, vol. 41, pp. 151-167. Cairns and his group have done much pioneering work on the biological monitoring of water pollution, of which this paper is just one example. See also R. E. Sparks; J. Cairns, Jr. ; and A. G. Heath, *The use of bluegill breathing rates to detect zinc*.
Calder, Nigel, ed. 1968. "Unless peace comes". *Viking*, New York. Effects of future weapons systems.
Campbell, Jan. 1974. "Human mismanagement as a major factor in the Sahelian drought tragedy: Diagnosis of a famine". *The Ecologist*, vol. 4, pp. 164-169 (June). Discusses how "even before the drought took its toll the animal and human population of the Sahel was outstripping its food production."
Campbell, W. J., and S. Martin. 1973. "Oil and ice in the Arctic Ocean: Possible large-scale interactions". *Science*, vol. 181, pp. 56-58 (July 6). Slow rate of biodegradation gives oil time to spread over large areas, reducing the reflectivity of sea ice.
Carefoot, G. L., and E. R. Sprott. 1967. *Famine on the wind*. Rand McNally, Chicago. On plant diseases (see especially material on the Irish potato famine).
Carlson, C. A., Jr. 1971. Impact of waste heat on aquatic ecology. In *Power generation and environmental change*, D. A. Berkowitz and A . M. Squires , eds. M.I.T. Press, Cambridge, Mass., pp. 351-364. Good survey of the effects of waste heat discharged to water.
Carson, Rachel. 1962. *Silent spring*. Houghton Mifflin, Boston. This classic, thought to be alarmist by many when it was published, now appears to have understated the pesticide problem in some respects.

Casida, J. E., R. A. Gray, H. Tilles. 1974. "Thiocarbamate sulfoxides: potent, selective, and

biodegradable herbicides". *Science*, vol. 184, pp. 573-574 (3 May).
CEQ. See Council on Environmental Quality.
Chambers, D. L., R. T. Cunningham, R. W. Lichty, and R. B. Thrailkill, 1974. "Pest control by attractants: a case study demonstrating economy, specificity, and environmental acceptability". *BioScience*, vol. 24, pp. 150-152. Describes work on fruit flies (Tephritidae), with emphasis on the oriental fruit fy, Dacus dorsalis.
Charney, J., P. H. Stone, and W. J. Quirk. 1975. "Drought in the Sahara: A biogeophysical feedback mechanism". *Science*, vol. 187, pp. 434435 (February 7).
Chýlek, P., and J. Coakley. 1974. "Aerosols and climate". *Science*, vol. 183, pp. 75-77 (January 11). Demonstrates that particles can cause atmospheric heating as well as cooling.
Cicerone, R. J.; R. S. Stolarski; and S. Waters. 1974. "Stratospheric ozone destruction by man-made chlorofluoromethanes". *Science*, vol. 185, pp. 1165-1167 (September 27). Establishes importance of chlorofluorocarbons as a threat to ozone.
Clark, John R. 1969. "Thermal pollution and aquatic life". *Scientific American*, March. (Scientific American offprint 1135, W. H. Freeman and Company, San Francisco.)
Cloudsley-Thompson, J. L. 1974. "The expanding Sahara". *Environmental Conservation*, vol. 1, spring, pp. 5-13. Interesting ecological summary article emphasizing role of human impact in expansion.
Coan, Gene. 1971. "Oil pollution". *Sierra Club Bulletin*, March, pp. 13-16. Discussion of the immediate and long-term effects of oil pollution on marine life by a marine biologist. Good bibliography.
Coello, W.; Z. A. Saleem; and M. A. Q. Khan. 1974. Ecological effects of lead in auto-exhaust. In *Survival in toxic environments*, M. Khan and J. Bederka, eds. Academic Press New York. Details on concentrations and toxicities.
Cole, LaMont C. 1966. Complexity of pest control in the environment. In *Scientific aspects of pest control National Academy of Sciences*National Research Council, Washington, D.C., publication 1402.
Colton, J. B., Jr.; F. D. Knopp; and B. R. Burns. 1974. "Plastic particles in surface waters of the northwestern Atlantic". *Science*, vol. 185, pp. 491-497 (August 9). Detailed review. At the moment, the threat from plastics appears to be minor compared to that from other pollutants.
Commoner, Barry. 1967. "Science and survival". *Viking*, New York. Technology and survival (see especially the material on the ecological effects of thermonuclear war).
-----. 1975. Threats to the integrity of the nitrogen cycle: Nitrogen compounds in soil, water, atmosphere, and precipitation. In *The changing global environment*, S. F. Singer, ed. Reidel, Dordrecht, Netherlands, pp. 340-366. Somewhat controversial assessment, reprinted without change from 1970 version.
Constable, J. D.; R . E. Cosk; M. Meselson; and A. H. Westing. 1974. "AAAS and NAS herbicide reports". *Science*, vol. 186, pp. 584-585 (November 15). Points out great similarities, although the American Association for the Advancement of Science thought damage to inland forests was greater.
Cooke, A. S. 1973. "Shell-thinning in avian eggs by environmental pollutants". *Environmental Pollution*, vol. 4, pp. 85-157. A fine review with a superb bibliography (see especially the "note added in proof" on a recent controversy about the source of shell-thinning).
Cooper, D. F., and W. C. Jolly. 1969. *Ecological effects of weather modification*. University

of Michigan, School of Natural Resources, Ann Arbor. This report, sponsored by the United States Department of the Interior, is an excellent, balanced summary of possible consequences of purposeful weather modification and contains much material related to the effects of gradual climatic change. Good bibliography.
Cope, O. B. 1971. "Interactions between pesticides and wildlife". *Annual Review of Entomology*, vol. 16, pp. 325-364. Complementary to D. Pimentel, Ecological effects of pesticides on non-target species. Arrangement is according to effects.
Corbett, J. R. 1974. *The biochemical mode of action of pesticides*. Academic Press, London and New York. An excellent source for pesticide structures and physiological effects-technical but readable.
Cory, L.; P. Field; and W. Serat. 1970. "Distribution patterns of DDT residues in the Sierra Nevada mountains". *Pesticides monitoring journal* vol. 3, pp. 204-211. Pollution far from sources.
Cottam, Clarence. 1965. "The ecologist's role in problems of pesticide pollution". *BioScience*, vol. 15, pp. 457-462.
Coulson, J. C.; J. R. Deans; G. R. Potts; J. Robinson; and A. N. Crabtree. 1972. "Changes in organochlorine contamination of the marine environment of eastern Britain monitored by shag eggs". *Nature*, vol. 236, pp. 454-456 (April 28). Shows reduction.
Council for Agricultural Science and Technology. 1976. *Effect of increased nitrogen fixation on stratospheric ozone*. Report no 53. Iowa State University, Ames, Iowa. Report of an interdisciplinary scientific task force, containing critical review of magnitude of anthropogenic nitrogen fixation compared to natural processes and alternative estimates of ozone depletion from increased atmospheric N2O.
Council on Environmental Quality (CEQ). 1970. *Ocean dumping. Report to the president*, Government Printing Office, Washington, D.C. Analyzes present and anticipated trends in ocean dumping of wastes and recommends the formulation of a national policy for regulation.
------. 1971. *Environmental quality: Second annual report*. Government Printing Office, Washington, D.C. This report concentrates on the costs of environmental protection -- what is spent now and what will be needed in the future. Subsequent annual volumes are goldmines of information on topics covered in this chapter.
Cowell, E. B. 1976 Oil pollution of the sea. In R . Johnston, ed., *Marine pollution*, pp. 353-401. Concludes that added cancer risks from oil in seafoods must be very low, and that ecosystemic effects are likely to be much less than those of other pollutants such as heavy metals and chlorinated hydrocarbons.
Cox, James L. 1970. "DDT residues in marine phytoplankton: Increase from 1955 to 1969". *Science*, vol. 170, pp. 71-73 (October 2).
Crutzen, P. J. 1970. "The influence of nitrogen oxides on the atmospheric ozone content". *Quarterly Journal of the British Meteorological Society*, vol. 96, pp. 320-325. One of the pioneering papers in uncovering the threat to ozone.
-----. 1974. "Estimates of possible variations in total ozone due to natural causes and human activities". *Ambio*, vol. 3, no. 2, pp. 201-210. Quantitative results for ozone reduction caused by nuclear war, SSTs, Freons, and nitrogen fertilizer. An important and thorough paper.
Davidson, G. 1974. *Genetic control of insect pests*. Academic Press, New York. A good, brief review.

Davis, J. B., and R. L. Barnes. 1973. "Effects of soil-applied fluoride and lead on growth of loblolly pine and red maple". *Environmental Pollution*, vol. 5, pp. 35-44. Both toxins reduced growth of seedlings.
De Paul Bach, ed. 1964. *Biological control of insect pests and weeds*. Reinhold, New York. Covers one of the components of integrated control.
Diamond, Jared M. 1975. "The island dilemma: Lessons of modern biogeographic studies for the design of natural reserves". *Biological Conservation*, vol. 7, pp. 129-146. Applies the theory of island biogeography to understanding the number of species a system of reserves can support, what will happen with various patterns of habitat destruction, and what geometrical patterns of reserves would maximize the preservation of species.
Doane, Robert R. 1957. *World Balance Sheet*. Harper, New York. Source of data on land classification.
Dochinger, L. S., and C. E. Seliskar. 1970. Air pollution and the chlorotic dwarf disease of Eastern white pine. *Forest Science*, vol. 16, pp. 46-55. This serious disorder is caused by ozone and sulfur dioxide, singly and in combination.
Dorst, Jean. 1970. *Before nature dies*. Wm. Collins Sons, London. A very interesting popular treatment of many of the topics discussed in this chapter.
Dugan, P. R. 1972. "Biochemical ecology of water pollution". *Plenum*, New York. Brief, highly readable, well done. (Available in paperback, 1975).
Eckholm, E. P. 1975. "Desertification: A world problem". *Ambio*, vol. 4, no. 4, pp. 137-145. Calls for a radical transformation of life in the edges of deserts.
-----. 1976. *Losing ground: Environmental stress and world food prospects*. Norton, New York. A fine popular treatment, indicative of a growing awareness of the ecological constraints on agriculture among nonecologists. Chapter 4 on desertification is especially relevant to this chapter.
Edwards, Clive A. 1969. "Soil pollutants and soil animals". *Scientific American*, April. (Scientific American offprint 1138, W. H. Freeman and Company, San Francisco.)
Egler, F. E. 1964. "Pesticides -- in our ecosystem". *American Scientist*, vol. 52, pp. 110-136. An outspoken ecologist discusses the problems of getting ecologically sophisticated control of pests.
----- and S. R. Foote. 1975. *The plight of the rightofway domain*. 2 vols. Futura Media Service, Mt. Kisco, N.Y. Offbeat but most interesting discussion of the mismanagement of the vegetation on more than 200 million hectares in the United States along the sides of highways and railheads, under electric transmission lines, and the like. Notes the "six principles of intelligent management."
Ehrlich, Paul R., and L. E. Gilbert. 1973. "Population structure and dynamics of the tropical butterfly Heliconius ethilla". *Biotropica*, vol. 5, pp. 69-82. Shows how relatively large areas of forest are necessary for the persistence of some insect populations.
Eigner, Joseph. 1975. *Unshielding the sun . . . environmental effects. Environment*, vol. 17 (April/May), pp. 15-18. Potential effects of ozone depletion on phytoplankton, insects, DNA.
Eisner, T.; L. B. Hendry; D. B. Peakall; and J. Meinwald. 1971. "2,5-Dichlorophenol (from ingested herbicide?) in defensive secretion of grasshopper". *Science*, vol. 172, pp. 277-278 (April 16). Evidence that grasshoppers ingest herbicide and use it to defend themselves against other insects.

Epstein, Samuel S. 1970. "NTA". *Environment*, vol. 12, no. 7, pp. 3-11. On nitrilotriacetic acid as a substitute for phosphorus in detergents.
-----. 1972. "Toxicological and environmental implications of the use of nitrilotriacetic acid as a detergent builder". 2 pts. *International Journal of Environmental Studies*, vol. 2, pp. 291-300, and vol. 3, pp. 13-21. More on NTA.
Fabacher, D. L., and H. Chambers. 1974. "Resistance to herbicides in insecticide resistant mosquitofish, Gambusia affinis". *Environmental Letters*, vol. 7, pp. 15-20. First instance of fishes' becoming resistant to herbicides entering water from treated fields.
Farvar, M. T., and J. P. Milton, eds. 1972. *The careless technology: Ecology and international development*. Natural History Press, Garden City, N.Y. A wide diversity of articles on human assaults on ecosystems in LDCs. Some articles now dated (they are based on conference papers given in 1968).
Fimreite, N.; W. Holsworth; J. Keith; P. Pearce; and I. Gruchy. 1971. "Mercury in fish and fish-eating birds near sites of industrial contamination in Canada". *Canadian Field Naturalist*, vol. 85, pp. 211-220. Mercury concentrations in fishes and fish-eating birds positively correlated with trophic level.
Fisher, J.; N. Simon; and J. Vincent. 1969. "Wildlife in danger". *Viking*, New York. A comprehensive summary of the state of endangered species of vertebrate animals and plants. Readable and well illustrated.
Fisher, N. S.; E. J. Carpenter; C. C. Remsen; and C. F. Wurster. 1974. Effects of PCB on interspecific competition in natural and gnotobiotic phytoplankton communities in continuous and batch cultures. *Microbial Ecology*, vol. 1, pp. 39-50. Toxicity of PCBs to a diatom greatest when it was in competition with other species.
Fletcher, W. W. 1974. *The pest war*. Wiley, New York. Despite its ecological naiveté, this book contains some useful information.
Flohn, Hermann. 1969. *Climate and weather*. McGraw-Hill, New York. A fine summary.
Foster, G. G.; M. J. Whitten; T. Prout; and R. Gill. 1972. "Chromosome rearrangements for the control of insect pests". *Science*, vol. 176, pp. 875-880 (May 26). Describes possible use of insect strains with compound chromosomes (artificially produced chromosomes with two homologous arms attached to the same centromere) to control pest populations.
Frink, C. 1967. "Nutrient budget: Rational analysis of eutrophication in a Connecticut lake". *Environmental Science Technology*, vol. 1, p. 425. Technical investigation of nitrogen and phosphorus concentrations in bottom sediments.
Frost, Justin. 1969. *Earth, air, water. Environment*, vol. 11, pp. 14-33. Discusses the major role of the atmosphere in distributing chlorinated hydrocarbons.
Frost, P. G. H.; W. R. Siegfried; and J. Cooper. 1976. "Conservation of the jackass penguin [Spheniscus demersus (L.)]". *Biological Conservation*, vol. 9, pp. 79-99. Oil pollution is just one of several factors leading to decline of this species.
Garrels, R. M.; F. T. Mackenzie; and C. Hunt. 1975. *Chemical cycles and the global environment*, Kaufmann, Los Altos, Calif. Concise, quantitative treatment of origins and fates of chlorinated hydrocarbons and petroleum in the global environment.
Georghiou, G. P. 1971. Resistance of insects and mites to insecticides and acaricides and the future of pesticide chemicals. In *Agricultural chemicals*, J. E. Swift, ed. University of California, Division of Agricultural Sciences, Berkeley, pp. 112-124.
Gibbons, J. W., and R. R. Sharitz. 1974. "Thermal alteration of aquatic ecosystems". *Amencan Scientist*, vol. 62, pp. 660-670 (November/December). Response of aquatic

communities to particularly intense thermal loadings.

-----, (ods.) 1974. *Thermal ecology*. USAEC, Technical Information Center, Springfield, Va. A wide-ranging symposium on the responses of organisms and communities to thermal stress. See especially papers by McKenny and Dean and Thatcher on combinations of thermal and heavy-metals stresses, and Stearney et al. on the effects of thermal stress on nonaquatic elements of each.

Giese, R. L.; R. M. Peart; and R. T. Huber. 1975. "Pest management". *Science*, vol. 187, pp. 1040-1052 (March 21). Useful introductory discussion and description of systems approach to control of alfalfa pest.

Gilmour, C. M., and O. N. Allen, eds. 1965. *Microbiology and soil fertility*. Oregon State University Press, Corvallis.

Glass, Bentley. 1962. "The biology of nuclear war". *American Biology Teacher*, vol. 24, pp. 407-425 (October). An early evaluation of the possible results of nuclear war.

Goldberg, E. G. 1972. *A guide to marine pollution*. Gordon and Breach, New York. Chapters on halogenated hydrocarbons, petroleum, organic and inorganic chemicals, nutrients, suspended solids, radioactivity, test organisms and monitoring systems.

Goodland, R. J. A., and H. S. Irwin. 1975. *Amazon jungle. Green hell to red desert*. American Elsevier, New York. Summarizes history, biota, ecology, ethnology of Amazonia and possible repercussions of its development.

Gordon, A. G., and E. Gorham. 1963. Ecological aspects of air pollution from an iron-sintering plant at Wawa, Ontario. *Canadian Journal of Botany*, vol. 41, pp. 1063-1078. Detailed study of a severe localized air pollution problem.

Graham, Frank Jr. 1966. *Disaster by default: Politics and water pollution*. M. Evans, New York.

Grobecker, A.; S. Coroniti; and R. Cannon. 1974. "The effects of stratospheric: pollution by aircraft". Technical Information Service, Department of Transportation, Springfield, Va., DOT-TST-7550. Written obscurely enough to be widely misinterpreted as reassuring on the effects of a fleet of SSTs. It actually confirms the seriousness of the threat to ozone by a large fleet.

Groth, E. III. 1975. "Increasing the harvest". *Environment*, January/February. A fine review article with much material on the ecological cost of agriculture. The bibliography is most useful, especially the references on crop losses.

Gruener, N., and R. Toeplitz. 1975. "The effect of changes in nitrate concentration in drinking water on methemoglobin levels in infants". *International Journal of Environmental Studies*, vol. 7, pp. 161-163.

Guenzi, W. D., ed. 1974. "Pesticides in soil and water". *Soil Science Society of America*, Madison, Wis. Deals with many technical aspects of pesticide behavior in soil and surface water.

Gwynne, Peter. 1976. "Doomed jungles?" *International Wildlife*, July/ August, pp. 36-47. Fine article on the values of tropical forests, now rapidly being destroyed.

Hallsworth, E. G., and W. A. Adams. 1973. "The heavy metal content of rainfall in the East Midlands". *Environmental Pollution*, vol. 4, pp. 231-235. Soils of England's midlands are receiving regular additions of lead, vanadium, manganese, chromium, nickel, copper, and molybdenum from rain.

Hamelink, J. L.; R. C. Waybrant; and R. C. Ball. 1971. "A proposal: Exchange equilibria

control the degree chlorinated hydrocarbons are biologically magnified in lentic environments". *Transactions, American Fisheries Society*, vol. 100, pp. 207-214. Describes exchanges between water and fat.
Hammond, Allen L. 1971. "Phosphate replacements: problems with the washday miracle". *Science*, vol. 172, pp. 361-363 (April 23).
----- and T. H. II. Maugh 1974. "Stratospheric pollution: Multiple threats to Earth's ozone". *Science*, vol. 186, pp. 335-338 (October 25). Concise summary of relevant reactions and potential consequences.
Haney, A., and R. L. Lipsey. 1973. "Accumulation and effects of methyl mercury hydroxide in a terrestrial food chain under laboratory conditions". *Environmental Pollution*, vol. 5, pp. 305-316. Significant effects on both plants and the aphids feeding on them; high concentrations.
Hanson, W. C. 1967. "Cesium-137 in Alaskan lichens, caribou and eskimos". *Health Physics*, vol. 13, pp. 383-389. Classic paper showing concentration by food chains.
Haque, R., and V. H. Freed, eds. 1975. *Environmental dynamics of pesticides*. Plenum, New York. Contains a number of important review articles. Highly technical.
Hardin, Garrett. 1971. "Nobody ever dies of overpopulation". *Science*, vol. 171, p. 527 (February 12). A hard-hitting editorial pointing out the relationship of large population size with high death rates.
Harper, J. 1956. "Ecological aspects of weed control". *Outlook on agriculture*, vol. 1, pp. 197-205. An early paper predicting the development of resistance to herbicides by weeds.
-----. 1956. "The evolution of weeds in relation to herbicides". *Proc. British Weed Control Conference*, vol. 3, pp. 179-188. A basic source on the potential for the evolution of herbicide-resistance.
Harriss, R. C.; D. B. White; and R. B. McFarlane. 1970. "Mercury compounds reduce photosynthesis by plankton". *Science*, vol. 170, pp. 736-737 (November 13).
Hart C. W., Jr., and S. L. H. Fuller, ods. 1974. *Pollution ecology of freshwater invertebrates*. Academic Press, New York. Arranged by organism; technical.
Harvey, G. R.; H. P. Miklas; V. T. Bowen; and W. G. Steinhauer. 1974. "Observations on the distribution of chlorinated hydrocarbons in Atlantic Ocean organisms". *Journal of Marine Research*, vol. 32, pp. 103-118. Data do not support food-chain magnification.
Harward, M., and M. Treshow. 1975. "Impact of ozone on the growth and reproduction of understory plants in the aspen zone of western U.S.A". *Environmental Conservation*, vol. 2, pp. 17-23. Significant effects found at 15 pphm and lower.
Harwood, R. F. 1975. "Economics, esthetics, environment and entomologists: The tussock moth dilemma". *Environmental Entomology*, vol. 4, pp. 171-174. Interesting account of the battle over the use of DDT.
Hasler, Arthur D. 1975. Man-induced eutrophication of lakes. In *The changing global environment*, S. F. Singer, ed. Reidel, Dordrecht, Netherlands, pp. 383-399. Reprint of an excellent 1970 survey.
Hay, Edwards. 1970. "Smog, the quiet killer". *American Forests*, vol. 76, April, pp. 16-19. Contains statistics on smog damage to San Bernardino National Forest.
Hays, J. D.; John Imbrie; and N. J. Shackleton. 1976. "Variations in the Earth's orbit: Pacemaker of the ice ages". *Science*, vol. 194, pp. 1121-1132 (10 December). Studies of ocean floor sediments laid down over a period of almost half a million years reveal that much of the climatic variation during this span of time took place in phase with changes in

Earth's orbit having periods of 23,000, 42,000 and 100,000 years. The prognosis, based on these orbital changes and ignoring anthropogenic influences, is for extensive Northern Hemisphere glaciation in the next several thousand years.

Hazeltine, W. 1972. "Disagreement on why brown pelican eggs are thin". *Nature*, vol. 239, pp. 410-411. Incorrectly disputes relationship between DDT and breeding failures in birds. (See also J. L. Lincer, "DDD-induced eggshell-thinning in the American kestrel".)

Heath, R. G.; J. W. Sparn; and J. F. Kreitzer. 1969. "Marked DDE impairment of mallard reproduction in controlled studies". *Nature*, vol. 224, pp. 47-48.

Hodgpeth, J. W. 1973. Protection of environmental quality in estuaries. In *Environmental quality and water development*, C. R. Goldman; J. McEvoy, III; and P. J. Richerson, eds. W. H. Freeman and Company, San Francisco, pp. 233-249. Thermal, chemical, and landfill effects.

Hendry, Peter. 1970. "Who's afraid of advanced technology?" *Ceres*, July/August, pp. 45-48. On integrated pest-control.

Henriksson, K.; E. Karppanen; and M. Helminen. 1966. "High residue of mercury in Finnish white-tailed eagles". *Ornis Fennica*, vol. 43, pp. 38-45. High levels reported in this and the following paper strongly indicate food-chain concentration.

-----. 1969. "The amounts of mercury in seals from lakes and seas". *Nordisk Hygienisk Tidskrift*, vol. 50, pp. 54-59.

Hess, W. N., ed. 1974. *Weather and climate modification*. Wiley, New York. Good survey articles.

Heyerdahl, Thor. 1971. "Atlantic ocean pollution and biota observed by the Ra expeditions". *Biological Conservation*, vol. 3, pp. 164-167. These are the more detailed observations on which Heyerdahl's valuable publicizing of oceanic pollution were based.

-----. 1975. "How to kill an ocean". *Saturday Review*, November 29, 1975, pp. 12-18. A popular overview of the threat to the marine environment.

Hickey, J., and D. Anderson. 1968. "Chlorinated hydrocarbons and eggshell changes in raptorial and fish-eating birds". *Science*, vol. 162, pp. 271-273 (October 11). Correlation of eggshell change with presence of chlorinated-hydrocarbon residue.

Hill, Dennis S. 1975. *Agricultural insect pests of the tropics and their control*. Cambridge University Press, London. Extensive bibliography.

Hills, Lawrence D. 1969. "Farming with free fertility for profit". *Journal of the Soil Association*, October. How treated sewage can be successfully used as fertilizer.

Holden, Constance. 1976. "Mirex: Persistent pesticide on its way out". *Science*, vol. 194, pp. 301-303 (October 15). Recent paper on the fire-ant-mirex controversy.

Holdren, John P. 1971. Global thermal pollution. In *Global ecology*, John P. Holdren and Paul R. Ehrlich, eds. Calculation of ultimate thermal limits using the crudest model of Earth's heat balance.

----- and Paul R. Ehrlich, eds. 1971. *Global ecology: Readings toward a rational strategy for man*. Harcourt Brace, Jovanovich, New York. Numerous papers in this collection elaborate on points discussed in this chapter.

Holdren, John P., and P. Herrera. 1972. *Energy*. Sierra Club Books, New York. Contains good discussion of local, regional, and global thermal pollution.

Hollin, John T. 1965. "Wilson's theory of ice ages". *Nature*, vol. 208, pp. 12-16 (October 2). Describes a partial check of Wilson's ice-age theory.

Holt-Jensen, A. 1973. "Acid rains in Scandinavia". *Ecologist*, vol. 3, pp. 378-382 (October). Review article with good maps.
Holton, J. R. 1972. *An introduction to dynamic meteorology*. Academic Press, New York. Good text for the serious and mathematically inclined student of meteorology/climatology.
Hudson, Norman. 1971. *Soil conservation*. Cornell University Press, Ithaca, N.Y. A comprehensive text on erosion and its prevention.
Huffaker, C. B. 1970. Summary of a pest management conference: A critique. In *Concepts of pest management*, R. L. Rabb and J. E. Guthrie . North Carolina State University Press, Raleigh.
-----. 1971. The ecology of pesticide interference with insect populations (upsets and resurgences in insect populations). In *Agricultural chemicals, harmony or discord for food, people, environment*, J. E. Swift , ed., University of California Division of Agricultural Sciences, Berkeley, pp. 92-104. A fine discussion of how pesticides upset the "balance of nature."
-----. 1971. "Biological control and a remodeled pest control technology". *Technology Review*, vol. 73, June, pp. 30-37. An excellent summary paper.
-----, ed. 1971. *Biological control*. Plenum, New York. A comprehensive bible of ecologically sane pest-control practices. Ought to be read by everyone interested in alternatives to today's disastrous pesticide practices.
-----, M. van den Vrie, and J. A. McMurtry. 1969. "The ecology of tetranychid mites and their natural control". *Annual Review of Entomology*, vol. 14, pp. 125-174. See especially the comparison of the reproductive-stimulation and predator-inhibition hypothesis.
-----. 1970. "Ecology of tetranychid mites and their natural enemies: A review". Pt. 2, Tetranychid populations and their possible control by predators: An evaluation. *Hilgardia*, vol. 40, pp. 391-458.
Hughes, J. D. 1975. *Ecology of ancient civilizations*, Univ. of New Mexico Press. Fascinating study of the environmental impact of early civilizations.
Hunt, Eldridge. G. 1966. "Biological magnification of pesticides, Symposium an scientific aspects of pest control". National Academy of Sciences-National Research Council, Washington, D.C., pp. 252261. Information on the buildup of pesticides in food chains.
Hurlbert, S.; M. Mulla; and H. Wilson. 1972. "Effects of an organophosphorus insecticide on phytoplankton, zooplankton, and insect populations of fresh-water ponds". *Ecological Monographs*, vol. 42, pp. 269-299. Discusses differential susceptibility of phytoplankton and zooplankton; useful bibliography.
Hutnik, R. J., and. G. Davis, eds. 1973. *Ecology and reclamation of devastated land*. 2 vols. Gordon and Breach, New York. Technical papers on properties and repair of land subject to strip-mining, polluted with mine tailings, and so forth. Technical.
Ignoffo, C. M. 1975. Entomopathogens as Insecticides. In *Insecticides of the future*, M. Jacobson, ed. Dekker, New York, pp. 23-40. Discusses potential of microbial pathogens as insecticides.
IMOS. *See*Interagency Task Force on Inadvertent Modification of the Stratosphere.
Institute of Ecology (TIE). 1972. *Man in the living environment*. Report of the Workshop of Global Ecological Problems. University of Wisconsin Press, Madison. Much important material on the relationship of population growth to environmental problems. The material on depletion of phosphorus supplies has since been shown to be overly pessimistic.
Interagency Task Force on Inadvertent Modification of the Stratosphere (IMOS). 1975.

Fluorocarbons and the environment. Government Printing Office, Washington, D.C., NSF 75403. Federal scientific task force finds "legitimate cause for concern" that fluorocarbon aerosol propellants and refrigerants are damaging Earth's ozone shield, with potentially serious effects on health, ecological systems, and climate.

Jackson, R. D.; S. B. Idso; and J. Otterman. 1975. "Surface albedo and desertification". *Science*, vol. 189, pp. 1012-1015 (September 19). Controversy over the relations among vegetation, surface albedo, and surface temperature.
Jacobson, M., ed. 1975. *Insecticides of the future*. Dekker, New York. See especially articles on microbial insecticides and manipulation of sex pheromones and growth and development hormones.
Jahns, R. H. 1968. "Geologic jeopardy". *Texas quarterly*, vol. 11, no. 2, pp. 69-83. Deals with geological hazards whose impact may be intensified by overpopulation. (Reprinted in John P. Holdren and Paul R. Ehrlich, eds., Global ecology.)
Jahoda, J. C., and D. L. O'Hearn. 1975. "The reluctant Amazon basin". *Environment*, October. A good review of the potential for development and disaster.
Janzen, D. H. 1970. "The unexploited tropics". *Bulletin of the Ecological Society of America*, September, pp. 4-7. A brief classic on the ecology of tropical agriculture.
-----. 1973. "Tropical agroecosystems". *Science*, vol. 182, pp. 1212-1214 (December 21). A brilliant summary of the problems of tropical agriculture and what temperate-zone rations do to exacerbate them. Good bibliography.
Johnston, D. W. 1974. "Decline of DDT residues in migratory songbirds". *Science*, vol. 186, pp. 841-842 (November 29).
Johnston, H. S. 1971. "Reduction of stratospheric ozone by nitrogen oxide catalysts from SST exhaust". *Science*, vol. 173, pp. 517-522 (August 6). The original paper showing the plausibility of a nitrogen-oxide threat to the ozone layer. Its distinguished author was strongly criticized and even ridiculed by SST proponents, but subsequent reviews by impartial bodies completely upheld his results.
-----. 1974. "Photochemistry in the stratosphere-with applications to supersonic transports". *Acta Astronautica, vol. 1, pp. 135-136 (January/February). Excellent technical introduction to the ozone-SST problem by the pioneer in the field.*
-----. 1976. *Analysis of the independent variables in the perturbation of stratospheric ozone by nitrogen fertilizers*. University of California Lawrence Berkeley Laboratory Report LBL-5488. Discusses ranges of uncertainties in crucial parameters governing ozone depletion due to increases in fertilizer use.
-----, G. Whittier, and J. Birks. 1973. "Effect of nuclear explosions on stratospheric nitric oxides and ozone". *Journal of Geophysical Research*, vol. 78, p. 6107.
Johnston, R., ed. 1976. *Marine pollution*. Academic Press, New York. Up to date and comprehensive.
Jones, D. P., and M. E. Solomon, eds. 1974. *Biology in pest and disease control*. Wiley, New York. This symposium volume covers a vast diversity of topics from plant breeding for resistance to genetic and behavioral control of insects-including such offbeat topics as biological control of pests in greenhouses.
Kahn, Herman. 1962. *Thinking about the unthinkable*. Horizon, New York. A good reply to

those who attacked Kahn personally over On thermonuclear roar rather than exposing the book's many flaws.
-----. 1968. *On escalation*. 2d ed. Penguin, Baltimore. An interesting analysis that reveals much about the thinking of military planners at the height of the Cold War.
-----. 1969. *On thermonuclear war*. 2d ed. Free Press, New York. The original "it wouldn't be so bad" book, first published in 1960 and hopelessly flawed by-among other things-the author's ignorance of ecology.
----- and A. J. Weiner. 1967. *The year 2000*. Macmillan, New York. An outstanding example of futurism that discounts problems of population, resources, and environment. The words *ecology* and *environment* do not appear in the index, which may explain in pert why Kahn seems to view the possibility of thermonuclear war with relative equanimity.
Kassas, M. 1970. Desertification versus potential for recovery in circumSaharan territories. In *Arid lands in transition*, American Association for the Advancement of Science, Washington, D.C. Short discussion of the human role in enlarging the Sahara and an extensive bibliography of the scientific literature on the subject.
Katan, J.; T. W. Fuhremann; and C. P. Lichtenstein. 1976. "Binding of [^{14}C] parathion in soil: A resssessment of pesticide persistence". *Science*, vol. 193, pp. 891-894 (September 3). A decrease of extractable residue in soils was accompanied by an increase of unextractable (bound) residues, indicating that the whole notion that organophosphates are nonpersistent should be reevaluated.
Kearney, P. C.; R. G. Marsh; and A, R. Isensee, 1969. Persistence of pesticide residues in soils. In *Chemical fallout*, M. W. Miller and G. G. Berg , eds., pp. 54-67. This is a basic source of estimates on persistence of pesticides under normal agricultural conditions.
Keeney, D. R., and W. R. Gardner. 1975. The dynamics of nitrogen transformations in the soil. In *The changing global environment*, S. F. Singer , ed. Reidel, Dordrecht, Holland, pp. 367-375.
Kellogg, W. W. 1974. Climatic feedback mechanisms involving the polar regions. In *Proceedings, of Climate of the Arctic*. University of Alaska, College Press, Fairbanks. Discussion of sensitivity of global climate to conditions in polar regions, and survey of phenomena that influence those conditions.
----- and S. H. Schneider. 1974. "Climate stabilization: For better or for worse?" *Science*, vol. 186, pp. 1163-1172 (December 27). Prospects for modifying climate both intentionally and inadvertently, and discussion of associated political problems.
Kenaga, E. E. 1972. Factors related to bioconcentration of pesticides. In *Environmental toxicology of pesticides*, F. Matsumura, G. M. Boush and T. Misuto, eds., Academic Press, New York. Levels and mechanisms discussed.
Ketchum, Bostwick H., ed. 1972. *The water's edge: Critical problems of tie coastal zone*. M.I.T. Press, Cambridge, Mass. Proceedings of a workship on human impacts on fragile coastal ecosystems and on legal and management aspects.
Khan, M. A. Q., and J. P. Bedurka, eds. 1974. *Survival in toxic environments*. Academic Press, New York. Rather technical papers-see especially those of Hodgson and of Plapp on mechanisms of pesticide-resistance in insects.
Klechkovskii, V.; G. Polikarpov; and R. Aleksakhin, eds. 1973. *Radioecology*. Wiley, New York. Translation of a Soviet symposium with papers on terrestrial and aquatic systems.
Knabe, W. 1976. "Effects of sulfur dioxide on terrestrial vegetation". *Ambio* vol. 5, no. 5-6, p. 213-218. Mechanisms for SO2 effects on ecosystems and concentrations at which various

effects manifest themselves.
Kohl, D. H.; G. B. Shearer; B. Commoner. 1971. Fertilizer nitrogen contribution to nitrate in surface water in a cornbelt watershed. *Science*, vol. 174, pp. 1331-1334 (October 24).
Kolb, C. E. 1975. The depletion of stratospheric ozone. *Technology Review*, vol. 78, no. 1, pp. 39-47. Good, concise review.
Kondratyev, K. Ya. 1965. *Radiative heat exchange in the atmosphere*. Pergamon, London. Essemial for the serious student of physical climatology.

Kontogiannis, J. E., and J. C. Barnett. 1973. The effect of oil pollution on survival of the tidal pool copepod, "*Tigriopus californicus*". *Environmental Pollution*, vol. 4, pp. 69-79. Oil lowers survival rate both through direct toxicity and by acting as a barrier to oxygen transfer between air and water.
Kouyoumjian, H. H., and R. F. Uglow. 1974. Some aspects of the toxicity of p,p'-DDT, p,p'-DDE, and p,p'-DDD to the freshwater planarian *Polycelis felina* (Tricladida). *Environmental Pollution*, vol. 7, pp. 103-109. Nervous-system effects observed.
Kuhr, R. J., and H. W. Dorough. 1976. *Carbamate insecticides: Chemistry, biochemistry and toxicology*. CRC Press, Cleveland. Comprehensive and technical.
Lamb, H. H. 1972. *Climate: Past, present, and future*. Methuen, London.
Laven, H.; J. Cousserans; and G. Guille. 1972. "Eradicating mosquitoes using translocations: A first field experiment". *Nature*, vol. 236, pp. 456-457 (April 28). Reports successful test of introduced genetic semisterility to control a natural population.
Leach, J. H., and S. J. Nepszy. 1976. "The fish community in Lake Erie". *Journal of the Fisheries Research Board of Canada*, vol. 33, no. 3, pp. 622-638. Detailed discussion of roles of overfishing, eutrophication, and other factors in changing species composition.
Liang, T., and E. P. Lichtenstein. 1974. "Synergism of insecticides by herbicides: Effect of environmental factors". *Science*, vol. 186, pp. 1128-1130 (December 20). Synergism of DDT and parathion by the herbicide atrazine varied with soil type. (For the original work on synergisms see Lichtenstein, Liang, and Anderegg, 1973. Synergism of insecticides by herbicides.)
Lichtenstein, E. P.; T. Liang; and B. Anderegg. 1973. "Synergism of insecticides by herbicides". *Science*, vol. 181, pp. 847-849 (August 31). This is the original paper. For more recent work, see Liang and Lichtenstein, *Synergism of insecticides by herbicides*.
Lichtenstein. E. P.; K. R. Schultz; T. W. Fuhremann: and T. T. Liang. 1969. "Biological interaction between plasticizers and insecticides". *Journal of Economic Entomology*, vol. 62, pp. 761-765. Demonstrates toxicity of PCBs to insects and shows that those compounds may increase the toxicity of dieldrin and DDT.
Likens, G. E., ed. 1972. *Nutrients and eutrophication: The limiting nutrient controversy*. Special symposium, vol. 1, American Society of Limnology and Oceanography. Allen Press, Lawrence, Kans.
----- and F. H. Bormann. 1974. "Acid rain: A serious regional environmental problem". *Science*, p. 184, pp. 1176-1179 (June 14). An excellent recent technical review.
-----, and N. M. Johnson. 1969. "Nitrification: Importance to nutrient losses from a cutover forested ecosystem". *Science*, vol. 163, pp. 1205-1206. Large increase in loss of nitrates documented for deforested area.
-----. 1972. "Acid rain". *Environment*, vol. 14, pp. 33-40 (March). A good review article for the layman.

-----, D. W. Fisher, and R. S. Pierce. 1970. "Effects of forest cutting and herbicide treatment on nutrient budgets in the Hubbard Brook watershed-ecosystem". *Ecological Monographs*, vol. 40, pp. 23-47. Detailed evaluation of the biogeochemical effects of deforestation.
Lincer, J. L. 1975. "DDE-induced eggshell-thinning in the American kestrel: A comparison of the field situation and laboratory results". *Journal of Applied Ecology*, vol. 12, pp. 781-793. Shows that the correlative relationship between DDE in the egg and eggshellthinning is the same for both captive experimental birds and the wild population. Good bibliography for eggshell-thinning controversy (which no longer exists; see Hazeltine, *Disagreement on why brown pelican eggs are thin*).
Lincoln, C.; W. P. Boyer; and F. D. Miner. 1975. "The evolution of insect pest management in cotton and soybeans: Past experience, present status, and future outlook in Arkansas". *Environmental Entomology*, vol. 4, pp. 1-7. Good history of control practices and problems.
Linden, O. 1975. "Acute effects of oil and oil/dispersant mixture on larvae of Baltic herring". *Ambio*, vol. 4, no. 3, pp. 130-133. Use of dispersant increases toxicity 50 to 100 times and greatly slows rate of diminution of toxicity.
Lockie, J. D.; D. A. Ratcliffe; and R. Balharry. 1969. "Breeding success and organo-chlorine residues in golden eagles in West Scotland". *Journal of Applied Ecology*, vol. 6, pp. 381-389. Shows increased breeding success correlated with a decline in organochlorine residues.
Loftas, Tony. 1971. "The unseen dangers of oil". *New Scientist*, February 4, p. 228. Concise account of the effects of oil pollution on marine ecology.
Lowry, W. P. 1967. "The climate of cities". *Scientific American*, August. Good introduction to the subject, well illustrated.
MacDonald, G. J. F. 1968. How to wreck the environment. In *Unless peace comes*, N. Calder, ed. Viking, New York, pp. 181-205. Describes weather modification for military purposes.
-----. 1975. Man, weather, and climate. In *Environment*, W. W. Murdoch , ed., 2d ed. Sinauer, Sunderland, Mass., pp. 381-396. Readable concise survey of human influences on climate.
Machta, Lester. 1973. Prediction of CO2 in the atmosphere. In *Carbon and the biosphere*, G. M. Woodwell and E. V. Pecan, eds. National Technical Information Service, Springfield, Va., USAEC CONF720510. Mathematical models and correlation with measurements.
McElroy, M. B.; S. C. Wofsy; J. E. Penner, and J. C. McConnell. 1974. "Atmospheric ozone: Possible impact of stratospheric aviation". *Journal of Atmospheric Sciences*, vol. 31, pp. 287-303. Another analysis confirming the seriousness of the threat to ozone by SSTs.
McElroy, M. B.; J. W. Elkins; S. C. Wofsy; and Y. L. Yung. 1976. , "Sources and sinks for atmospheric N2O". *Review of Geophysics and Space Physics*, vol. 14, pp. 143-150. Estimates of effects of fertilizer use on ozone.
McFarlane, R. B.; W. A. Glooschenko; and R. C. Harriss. 1972. "The interaction of light intensity and DDT concentration upon the marine diatom, Nitzschia delicatissima Cleve". *Hydrobiologia*, vol. 39, pp. 373-382. Strongest effects of DDT occurred at highest light intensities-just one of the complexities of pesticide-plankton interaction.
McLaughlin, S. B., Jr., and R. L. Barnes. 1975. "Effects of fluoride on photosynthesis and respiration of some south-east American forest trees". *Environmental Pollution*, vol. 8, pp. 91-95. Pines are more sensitive than hardwoods.
McMurtry, J. A.; C. B. Huffaker; and M. Van den Vrie. 1970. "Ecology of tetranychid mites

and their natural enemies: A review". Pt. 1, Tetranychid enemies: their biological characters and the impact of spray practices. *Hilgardia*, vol. 40, pp. 331-390. Insecticide spraying promotes spider mites to the status of major pests.
McNeil, M. 1964. "Lateritic soils". *Scientific American*, November. Author's pessimism about laterization and tropical agriculture is disputed by P. H. Sanchez and S. W. Buol, Soils of the tropics and the world food crisis.
-----. 1972. Lateritic soils in disturbed tropical environments: Southern Sudan and Brazil. In *The careless technology*, M. T. Farvar and J. P. Milton, eds. Natural History. Press, Garden City, N.Y. pp. 591-608.

Malmer, N. 1976. "Acid precipitation: Chemical changes in the soil". *Ambio*, vol. 5, no. 5-6, p. 231-234, Increases in leaching as influenced by acid rain and detailed soil properties. Potential for synergistic effects.
Malone, C. R. 1969. "Effects of diazinon contamination on an old-field ecosystem". *American Midland Naturalist*, vol. 82, pp. 1-27. Primary effects were on vegetation, not on insects!
Manabe, S. 1971. Estimates of future change of climate due to the increase of carbon dioxide concentration in the air. In *Man's impact on climate*, W. H. Matthews, W. W. Kellogg, and G. D. Robinson, eds., pp. 249-264. Significant temperature increases by the year 2000 could result from continued rapid growth in the use of fossil fuels.
----- and R. T. Weatherald. 1967. "Thermal equilibrium of the atmosphere with a given distribution of relative humidity". *Journal of Atmospheric Sciences*, vol. 24, pp. 241-259.
Marks, P. L., and F. H. Bormann. 1972. "Revegetation following forest cutting: mechanisms for return to steady-state nutrient cycling". *Science*, vol. 176, pp. 914-915 (May 26). Succession tends to minimize loss of nutrients from cutover systems.
Martin, J. H., and W. W. Broenkow. 1975. "Cadmium in plankton: Elevated concentration off Baja California". *Science* vol. 190, pp. 884-885 (November 28). Plankton concentration carried to approximately 3 times the levels found elsewhere, reasons unknown.
Martin, H., and C. R. Worthing. 1974. *Pesticide manual: Basic information on the chemicals used in active components of pesticides*. 4th ed. British Crop Protection Council. Alphabetically organized summary of structure, production, use, side effects, and so forth, of more than 500 compounds.
Martin, R. D., ed. 1975. *Breeding endangered species in captivity*. Academic Press, New York. A diversity of papers focusing on different species from Galapagos tortoises to Indian rhinos.
Marx, J. L. 1975. "Air pollution: Effects on plants". *Science*, vol. 187, pp. 731-733 (February 28). A good summary on ozone and other oxidants.
Marx, Wesley. 1967. *The frail ocean Coward*, McCann, New York. On human assaults on oceanic ecosystems.
-----. 1971. *Oilspill*. Sierra Club, San Francisco. A good overview for the layman.
Matsumura, Fumio. 1975. *Toxicology of insecticides*; Plenum, New York. Comprehensive, technical, good bibliographies.
----- and G. M. Boush. 1967. "Dieldrin: Degradation by soil microorganisms". *Science*, vol. 156, pp. 959-961 (May 19). Shows that a few microorganisms am break down dieldrin in the soil.
-----. 1968. "Breakdown of dieldrin in soil by a microorganism". *Nature*, vol. 219, pp. 965-

967. Identifies some of the products of dieldrin breakdown.
----- and T. Misato, eds. 1972. *Environmental toxicology of pesticides*. Academic Press, New York. Rather technical papers: considerable information on the situation in Japan.
Matthews, W. H.; W. W. Kellogg; and G. D. Robinson, eds. 1971. *Man's impact on climate*. M.I.T. Press, Cambridge, Mass. Background papers for the Study of Critical Environmental Problems (SCEP). Good introductions to major aspects of climate change.
Maugh, T. H. II. 1976. "Plant biochemistry: Two new ways to fight pests". *Science*, vol. 192, pp. 874-876 (May 28). Report on research aimed at using plants' natural defenses to protect crops against pests and diseases.
-----. 1976. "The ozone layer: The threat from aerosol cans is real". *Science*, vol. 194, pp. 170-172. (October 8). Confirmation of earlier studies on ozone destruction by chlorofluorocarbons.
Meggers, B. J. 1971. *Amazonia: Man and culture in a counterfeit paradise*. Aldine-Atherton, Chicago. A fine synthesis of culture and ecology.
-----. 1973. Some problems of cultural adaptation in Amazons, with emphasis on the pre-European period. In *Tropical forest ecosystems in Africa and South America: A comparative review*, B. J. Meggers, E. S. Ayensu, and W. D. Duckworth, eds., pp. 311-320. Smithsonian Institution, Washington, D.C. Excellent on several aspects of agriculture in tropical rain forest regions.
Menn, J. J., and F. M. Pallas. 1975. Development of morphogenetic agents in insect control. In *Insecticides of the future*, M. Jacobson, ed. Dekker, New York, pp. 71-88. Recent advances in the development of juvenile-hormone-type insecticides.
Metcalf, R. L., and W. H. Luckman, eds. 1975. *Introduction to insect pest management*. Wiley, New York. A first-class volume dealing with principles, techniques, and examples, with integration much superior to most multi-author volumes.
Miller, Albert. 1966. *Meteorology*. Merrill, Columbus, Ohio. Lucid introductory text with especially good treatment of energy balance.
Miller, M. W., and G. G. Berg, eds. 1969. *Chemical fallout: Current research on persistent pesticides*. Thomas, Springfield, Ill. An excellent volume containing a number of important papers.
Mitchell, H. H. 1961. *Ecological problems and postwar recuperation: A preliminary survey from the civil defense viewpoint*. U.S. Air Force project and research memorandum. A pioneering document, somewhat overoptimistic and now out-of-date.
Mitchell, J. M. 1975. A reassessment of atmospheric pollution as a cause of long-team changes of global temperature. In *The changing global environment*, S. F. Singer, ed., pp. 149-173. Argues that long-term warming is more likely than cooling, in consideration of combined effects of man-made carbon dioxide and particulate additions to the atmosphere. Also contends that the cooling trend that began in the 1940s must have had natural not human origin.
Molina, M. J., and F. S. Rowland. 1974. "Stratospheric sink for c. chloroflouromethanes: Chlorine atom catalyzed catalyzed of ozone". *Nature*, vol. 249, p. 810. The original paper showing that chlorofluorocarbons could be a threat to ozone.
Moll, K. D.; J. H. Cling and P. D. Mart. 1960. Postattack farm problems. Pt. 1, *The influence of major inputs on farm production*. Prepared for Office of Civil Defense Mobilization under the auspices of Stanford Research Institute (SRI), Menlo Park, Calif. Limited circulation (200 copies). One of the few attempts to investigate the consequences of

a nuclear attack systematically. Others by SRI include studies of the effects of a nuclear attack on railroad transport and the petroleum industry.
Moore, N. W., ed. 1966. "Pesticides in the environment and their effects on wildlife". *Journal of Applied Ecology*, vol. 3, June, supplement. This supplement contains many other interesting papers on pesticide ecology.
Moore, P. D. 1975. "Ozone over Britain". *Nature*, vol. 256, p. 537 (August 14). Short summary.
Moriarty, F., ed. 1975. *Organochlorine insecticides: Persistent organic pollutants*. Academic Press, New York. Monitoring, residues, economic analysis, and so forth. Technical.
Morris, B. F. 1971. "Petroleum: Tar quantities floating in the northwestern Atlantic taken with a new quantitative neuston net". *Science*, vol. 173, pp. 430-432 (July 30). Suggests that previous estimates of ocean pollution were too low.

Mosser, J. L.; N. S. Fisher, T. Teng; and C. F. Wurster. 1972. "Polychlorinated biphenyls: Toxicity to certain phyto-plankters". *Science*, vol. 175, pp. 191-192 (January 14). Shows differential susceptibility.
Mudd, J. B., and T. T. Kozlowski, eds. 1975. *Responses of plants to air pollution*. Academic Press, New York. A comprehensive set of up-to-date technical papers, good bibliographies.
Mulla, M. S., and L. W. Isaak. 1961. "Field studies on the toxicity of insecticides to the mosquito fish, Gambusia: affinis". *Journal of Economic Entomology*, vol. 54, pp. 1237-1242. Reports high toxicity to mosquito-eating fishes of pesticides used in mosquitoabatement programs.
Murphy, C. B., Jr. 1973. "Effect of restricted use of phosphate-based detergents on Onondaga Lake", *Science*, vol. 182, pp. 379-381, (October 26).
NAS. *See*National Academy of Sciences.
Nash, R. G., and E. H. Woolson. 1967. "Persistence of chlorinated hydrocarbon insecticides in soils". *Science*, vol. 157, pp. 924-927 (August 25). Gives long-term limits on persistence through studies in which pesticides were mixed uniformly into loam in experimental plots.
National Academy of Sciences (NAS). 1972. *Accumulation of nitrate*. NAS, Washington, D.C. Useful overview with extensive bibliography.
-----. 1973. *Biological impacts of increased intensities of solar ultraviolet radiation*. NAS, Washington, D.C. Good introduction and survey as of 1973, but already somewhat dated.
-----. 1974. *Effects of herbicides in South Vietnam Pt. A, Summary and conclusions*. NAS, Washington, D.C. This report may underestimate the damage to inland forests (see dissents at end) but otherwise represents a consensus of the scientific community (see Constable et al., AAAS and NAS herbicide reports).
-----. 1975. *Air quality and stationary source emissions control*. Government Printing Office, Washington, D.C. Thorough survey of the production and consequences of acid rain, the effects of oxides of nitrogen and sulfur on ecosystems, and other topics, prepared for Senate Committee on Public Works.
-----. 1975. *Environmental impact of stratospheric flight: Biological and climatic effects of aircraft emission in the stratosphere*. Washington, D.C. Documents seriousness of hazards to life that could result from heavy use of supersonic transports.
-----. 1975. *Understanding climatic change*. NAS, Washington, D.C. Good survey.
-----. 1975. *Long-term worldwide effects of multiple nuclear-weapons detonations*. NAS,

Washington, D.C. A badly flawed effort which still contains some useful information. Note also the report's letter of transmittal in which NAS president Philip Handler finds the report "encouraging" because it indicates that humanity (but not necessarily civilization) would survive a nuclear war! See also Philip Boffey M, Nuclear war: Federation disputes Academy on how bad effects could be.
-----. 1975. *Petroleum in the marine environment*. NAS, Washington, D.C. Comprehensive discussion of sources and effects.
National Center for Atmospheric Research (NCAR). 1975. *Atmospheric implications of energy alternatives*. NCAR, Boulder, Colo. Proceedings of a symposium containing up-to-date discussions of effects of heat, carbon dioxide, and particles.
Neilands, J. B.; G. H. Orians; E. W. Pfeiffer; A Vennema; and A. H. Westing . 1972. *Harvest of death: Chemical warfare in Vietnam and Cambodia*. Free Press, New York. See especially the chapter by Westing on Cambodia. Comprehensive coverage of the use of poison gases and herbicides. Highly recommended.
New Scientist. 1971. "Does killing weeds destroy the soil?" March 25, p. 663. On the effects of herbicides on soil bacteria.
Nuorteva, P., and Eritid Hasanen. 1972. Transfer of mercury from fishes to sarcosaprophagous flies, *Annales Zoologici, Fennici* vol. 9, pp. 23-27. Bioaccumulation occurs at levels of concentration in fishes that are higher than natural (0.17 ppm).
O'Connor, J. A.; D. G. Parbery; and W. Strauss. 1974. The effects of phytotoxic gases on native Australian plant species. Pt. 1, Acute effects of sulphur dioxide. *Environmental Pollution*, vol. 7, pp. 7-23. Sensitivity varies from species to species.
Odum, W. E. 1970. "Insidious alteration of the estuarine environment". *Transactions of the American Fisheries Society*, vol. 4, pp. 836-847. Summary of ecology of estuaries and how they are threatened. Good bibliography.
Oka, I. N., and D. Pimentel. 1976. "Herbicide (2,4-D) increases insect and pathogen pests on corn". *Science*, vol. 193, pp. 239-240 (July 16).
Olkowski, W.; H. Olkowski; R. van den Bosch; and R. Horn. 1976. "Ecosystem management: A framework for urban pest control". *BioScience*, vol. 26, no. 6 (June), pp. 384-389. Describes a program for protecting urban trees against pests, using integrated control methods.
Olson, B., and R. Cooper. 1976. Comparison of aerobic and anaerobic methylation of mercuric chloride by San Francisco Bay sediments. *Water research*, in press. Conversion of mercury to organic form.
Osburn, W. S., Jr. 1968. Forecasting long-range ecological recovery from nuclear attack. In *Proceedings of the symposium on post-attack recovery from nuclear war*. National Academy of Sciences-National Academy of Engineering-National Research Council, Washington, D.C. Good source of information and references, but like many establishment documents on this subject, overoptimistic because of its "one-at-a-time" approach to effects. (Updated in V. Schultz and F. Wicker, eds., *Ecological aspects of the nuclear age: Selected readings in radiation ecology*.)
Otterman, Joseph. 1974. "Baring high-albedo soils by overgrazing: A hypothesized desertification mechanism". *Science*, vol. 186, pp. 531-533 (November 8). Denuding by overgrazing bares highalbedo soils, cooling surface, decreasing lift of air for cloud formation and precipitation, and giving regional climatic desertification.
Pal, R., and M. J. Whitten, eds. 1974. *The use of genetics in insect control*. American

Elsevier Pub. Co., New York. A diverse collection of rather technical papers with heavy emphasis on mosquitoes, and a chapter on spider mites (which are not insects). Bibliographies give good access to the technical literature.
Peakall, D. B. 1967. "Pesticide-induced enzyme breakdown on steroids in birds". *Nature*, vol. 216, pp. 505-506. Indicates that DDT and dieldrin can change hormone metabolism and upset breeding.
-----. 1970. "Pesticides and the reproduction of birds". *Scientific American*, April, pp. 73-74. Semipopular account of the way chlorinated hydrocarbons affect breeding behavior and viability of eggs in birds. (For a more up-to-date and somewhat more technical treatment see D. B. Peakall, "Physiological effects of chlorinated hydrocarbons on avian species".)
-----. 1974. "DDE: Its presence in peregrine eggs in 1948". *Science*, vol. 183, pp. 673-674 (February 15). An important paper showing an association of DDT with thinning of eggshells as early as 1948.
-----. 1975. Physiological effects of chlorinated hydrocarbons on avian species. In *Environmental dynamics of pesticides*, R. Haque and V. Freed , eds. Plenum, New York, pp. 343-360. An excellent technical summary.

Pell, E. J., and E. Brennan. 1975. "Economic impact of air pollution on vegetation in New Jersey and an interpretation of its annual variability". *Environmental Pollution*, vol. 8, pp. 23-33. Describes great year-to-year variation in susceptibility of vegetation, possibly due to rainfall difference.
Perkins, E. J. 1976. The evaluation of biological response by toxicity and water quality assessments. In R. Johnston, ed., *Marine pollution*, pp. 505-585. Examines in detail how the effects of insults to marine ecosystems are determined.
Peterle, T. J. 1969. "DDT in Antarctic snow". *Nature*, vol. 224, pp. 620 (November 8). Tests indicate as much as 2400 MT of DDT could have accumulated in Antarctic snow by 1967.
Pfeiffer, E. W. 1973. "Post-war Vietnam". *Environment*, vol. 15, November, pp. 29-43. Describes attempts to recover from effects of war.
Pimentel, D. 1971. *Ecological effects of pesticides on non-target species. of Science and Technology, Executive Office of the President*, Washington, D.C. Comprehensive coverage of the literature to 1970, arranged chemical by chemical. See also O. B. Cope, Interactions between pesticides and wildlife, which has complementary arrangement of the information.
-----. 1973. "Extent of pesticide use, food supply, and pollution". *Journal of the New York Entomological Society*, vol. 81, pp. 13-33. Reports increases in crop losses in spite of increased pesticide use, due in part to "the practice of substituting insecticides for sound bioenvironmental pest control (for example, crop rotation and sanitation) and also to higher consumer standards."
-----, ed. 1975. *Insects, science, and society*. Academic Press, New York. See especially the article on pest management by L. D. Newsome, which has an informative discussion of integrated controls for soybean and cotton crops.
-----; E. C. Terhune R. D. Dyson-Hudson; S. Rochereau; R. Samis; E. A. Smith ; D. Denman; D. Reifschneider; and M. Shepard. 1976. "Land degradation: Effects on food and energy resources". *Science*, vol. 194, pp. 149-155 (October 8). Details losses of valuable U.S. topsoil to erosion and how they might be reduced.
Pinthus, M.; Y. Eshel; and Y. Shohori. 1972. "Field and vegetable crop mutants with

increased resistance to herbicides". *Science*, vol. 177, pp. 715-716 (August 25). Mutants of both wheat and tomato were found that were resistant to a triazine and an acetamide herbicide.
Polunin, Nicholas, ed. 1972. *The environmental future*. Macmillan, London. Contains many sections relevant to this chapter.
Porricelli, J. D.; V. F. Keith; and R. L. Storch. 1971. "Tankers and the ecology". *Transactions of the Society of Naval Architects and Marine Engineers* vol. 79, pp. 169-221. Contains much useful data on tanker incidents and accidents, traffic controls, terminals, and the like, in spite of the inappropriate "the" in the title?
Porter, R. D., and S. N. Wiemeyer. 1969. "Dieldrin and DDT: Effects on sparrow hawk eggshells and reproduction". *Science*, vol. 165, pp. 199-200 (July 11). Controlled feeding experiments.
Powell, N. A.; C. S. Sayce; and D. F. Tufts. 1970. "Hyperplasia in an estuarine bryozoan attributable to coal tar derivatives". *Journal of the Fisheries Research Board of Canada*, vol. 27, pp. 2095-2096. Study of abnormal growth in a small marine animal induced by oil pollution.
Powers, C. D.; R. G. Rowland; and C. F. Wurster. 1977. Dieldrininduced destruction of marine algal cells with concomitant decrease in size of survivors and their progeny. *Environmental pollution*, vol. 12, pp. 17-25. More on the effects of chlorinated hydrocarbon insecticides on marine phytoplankton.
Precoda Norman. 1975. "Left behind: Soviet mine wastes". *Environment*, vol. 17, no. 8, pp. 14-20. Results of strip-mining in the USSRnearly 40,000 hectares per year being devastated.
Priest, Joseph. 1973. *Problems of our physical environment*. AddisonWesley, Reading, Mass. Good introductory text to physical aspects of energy and environmental problems.
Ramanathan, V. 1975. "Greenhouse effect due to chlorofluorocarbons: Climatic implications". *Science*, vol. 190, pp. 50-51 (October 3). Simplified model shows mean global surface temperature could increase 0.9K by year 2000, because of the direct effect of chlorofluorocarbons in blocking outgoing terrestrial radiation.
Rappaport, Roy A. 1976. "Forests and num". *The ecologist*, vol. 6, no. 7 (August-September), pp. 240-246. An anthropologist describes the ecologically conscious behavior of swidden agriculturalists in New Guinea and makes some pertinent observations on bow technological societies have lost this awareness.
Rasool, S. I., ed. 1973. *Chemistry of the lower atmosphere*. Plenum, New York. Good discussion of climate modification by atmospheric pollution.
----- and S. H. Schneider. 1971. "Atmospheric carbon dioxide and aerosols: Effects of large increases on global climate". *Science*, vol. 173, pp. 138-141 (July 9). An increase of aerosol concentration by a factor of 4 could reduce surface temperature by as much as 3.5° K, enough to trigger an ice age, if sustained.
Ratcliffe, D. A. 1967. "Decrease in eggshell weight in certain birds of prey". *Nature*, vol. 215, pp. 208-210. Demonstrates rapid synchronous decline of eggshell thickness at the time chlorinated hydrocarbon pesticides were introduced. This was key evidence in establishing the role of these substances in the decline of bird populations.
-----. 1970. "Changes attributable to pesticides in egg breakage frequency and eggshell thickness in some British birds". *Journal of Applied Ecology*, vol. 7, pp. 67-115. Expands and updates a 1967 paper, giving more information on the temporal and geographic correlations between eggshell strength and use of chlorinated hydrocarbons. Extensive

bibliography.
Reck, R. A. 1976. "Stratospheric ozone effects on temperature". *Science*, vol. 192, pp. 557-559 (May 7). The temperature inversion at the stratopause could be weakened by substantial ozone depletion.
Reidinger, R. F., Jr., and D. G. Crabtree. 1974. "Organochlorine residues in golden eagles, United States, March 1964-July 1971". *Pesticides Monitoring Journal* vol. 8, pp. 3743. Suggests level of organochlorine poisoning remained rather constant between 1965 and 1970.
Reinert, Robert E. 1972. "Accumulation of dieldrin in an alga (*Scenedesmus obliquus*), Daphnia magna, and the guppy (*Poecilia reticulata*)". *Journal of the Fisheries Research Board of Canada*, vol. 29, pp. 1413-1418. Concentration factors directly from water were 1282 for the alga, 13,954 for D. magna and 49,307 for the guppy.
Revelle, R., and H. E. Suess. 1967. "Carbon dioxide between atmosphere and ocean and the question of an increase of atmospheric CO2 during the past decades". *Tellus*, vol. 9, no. 1, pp. 18-27.
Risebrough, R. W.; R. J. Huggett; J. J. Griffin; and E. D.Goldberg. 1968. "Pesticides: Transatlantic movements in the northeast trades". *Science*, vol. 159, pp. 1233-1236 (March 15). Important paper on aerial transport of chlorinated hydrocarbons.
Risebrough, R. W.; E. Huschenbeth; S. Jensen; and J. E. Portmann. 1972. *Halogenated hydrocarbons in A guide to marine pollution*, E. G. Goldberg , ed., Gordon and Breach, New York, pp. 1-17. Provides access to the literature on biconcentration (or the lack of it) by marine food chains.

Risebrough, R. W.; W. Walker II; T. T. Schmidt; B. W. de Lappe; and C. W. Connors . 1976. "Transfer of chlorinated biphenyls to Antarctica". *Nature*, vol. 264, pp. 738-739 (December 23/30). DDT and PCBs found in Antarctic snow and in penguin eggs.
Robinson, Alan S. 1976. "Progress in the use of chromosomal translocations for the control of insect pests". *Biological Reviews*, vol. 51, pp. 1-24. Good review, extensive bibliography.
Roe, Frank G. 1951. *The North American buffalo*. University of Toronto Press. Classic on destruction of a major element of an ecosystem.
Roelofs, Wendell. 1975. Manipulating sex pheromones for insect suppression. In *Insecticides of the future*, M. Jacobson, ed. Dekker, New York, pp. 41-59. Reviews various ways in which pheromones may be used to control insect populations.
Rosato. P., and 1). F. Ferguson. 1968. "The toxicity of endrin-resistant mosquito fish to eleven species of vertebrates". *BioScience*, vol. 18, pp. 783-784.
Roughgarden, J. 1978. *Theory of population genetics and evolutionary, ecology*; an introduction. Macmillan, New York. Chapter 22 on predation is highly pertinent to understanding the failure of many pesticide programs.
Rudd, Robert L. 1964. *Pesticides and the living landscape*. University of Wisconsin Press, Madison. The classic on ecological effects of pesticides.
Rukeyser, William S. 1972. "Fact and foam in the row over phosphates". *Fortune*, January. A business view of pollution from detergents and its regulation.
Ryan, R. G. 1970. "Resistance of common groundsel to simazine and atrazine". *Weed Science*, vol. 18, pp. 614-615. Resistance developed in a nursery where the herbicides had been in use for a decade.
Sabloff, J. 1971. The collapse of the classic Mayan civilization. In *Patient Earth*, J. Harte

and R. H. Socolow, eds. Holt, Rinehart and Winston, New York, pp. 16-27. Blames collapse on overintensive milpa agriculture (see also B. L. Turner, *Prehistoric intensive agriculture in the Mayan lowlands*).
Sanchez, P. A., and S. W. Buol. 1975. "Soils of the tropics and the world food crisis". *Science*, vol. 188, pp. 598-602 (May 9). Tends to minimize problems of laterization.
Sanders, H. O. 1970. "Toxicities of some herbicides to six species of freshwater crustaceans". *Water Pollution Control Federation Journal* vol. 42, no. 1, pp. 1544-1550.
----- and J. H. Chandler. 1972. "Biological magnification of a polychlorinated biphenyl (AroclorR 1254) from water by aquatic invertebrates". *Bulletin of Environmental Contamination and Toxicology*, vol. 7, pp. 257-263. Accumulation may be very rapid.
Schell, W. R., and R. L. Watters. 1975. "Plutonium in aqueous systems". *Health Physics*, vol. 29, pp. 589-597.
Schneider, S. H. 1974. "The population explosion: Can it shake climate?" *Ambio*, vol. 3, pp. 150-155. Readable survey of issues in human modification of climate.
-----. 1975. "On the carbon dioxide-climate confusion". *Journal of Atmospheric Sciences*, vol. 32, pp. 2060-2066 (November). Excellent review article, reconciling different estimates of effects of CO2 based on different models and assumptions.
----- and R. Dennett. 1975. "Climatic barriers to long-term energy growth". *Ambio*, vol. 4, no. 2, pp. 65-74. Good summary of potential effects of carbon dioxide, particles, and heat released from human activities.
-----, and R. E. Dickinson. 1974. "Climate modeling". *Reviews of Geophysics and Space Physics*, vol. 12, no. 3, pp. 447-493. Superbly comprehensive and authoritative review of the goals, techniques, and early results of climate modeling and correlation with experimental measurements. More than 200 references.
-----, and C. Mass. 1975. "Volcanic dusts, sunspots, and temperature trends: Climatic theories in search of verification". *Science*, vol. 190, pp. 741-746 (November 21). Much of the observed climatic variation of the past 400 years may possibly be explained by variations in the sun's output, combined with changes in amounts of volcanic dust in the atmosphere.
Schofield, C. L. 1976. "Acid precipitation: Effects on fish". *Ambio*, vol. 5, no. 5-6, pp. 228-230. Documents depletion of fish stocks as a consequence of acidification.
Schultz, V., and F. Wicker, eds. 1972. *Ecological aspects of the nuclear age: Selected reading in radiation ecology*. Technical Information Center, Oak Ridge, Tenn. Reprints important papers on radioisotope cycling, effects of ionizing radiation, and nuclear war, among others.
Scott, J. M.; J. H. Wiens; and R. R. Claeys. 1975. "Organochlorine levels associated with a common murre die-off in Oregon". *Journal of Wildlife Management*, vol. 39, pp. 310-320. High levels may have interacted with nutritional stress to cause an unusually high mortality level.
Scotto, J.; A. Kopf; and F. Urbach. 1974. Nonmelanoma skin cancer among Caucasians in four areas of the United States. *Cancer*, vol. M, p. 349. Major contribution to establishing the quantitative correlation between levels of ultraviolet radiation and skin cancer.
Scoville, Herbert. 1974. Nuclear explosives: Potential for ecological catastrophe. In *Air, water, earth, fire, Sierra Club*. Sierra Club, San Francisco, pp. 27-37.
Sears, Paul. 1971. An empire of dust. In *Patient Earth*, J. Haste and R. H. Socolow , eds. Holt, Rinehart and Winston, New York, pp. 2-15. A classic on the dust bowl.

Sellers, W. D. 1973. "A new global climate model". *Journal of Atmospheric Sciences*, vol. 12, pp. 241-254.
Seshachar, B. R. 1971. Problems of environment in India. In *Proceedings of joint colloquium on international environmental science*. Government Printing Office, Washington, D.C., 63-562. Documents human influence in expansion of Rajasthan (That) desert.
Seymour, A. H., ed. 1971. *Radioactivity in the marine environment*. National Academy of Sciences, Washington, D.C. A set of highly technical papers.
Shapley, Deborah. 1971. Mirex and the fire ant: Decline in fortunes of "perfect" pesticide. *Science*, vol. 172, pp. 358-360 (April 23).
Shea, Kevin P. 1968. "Cotton and chemicals". *Scientist and Citizen*, November. Gives details of the Azodrin situation.
Shell, W. R., and R. L. Watters. 1975. "Plutonium in aqueous systems". *Health Physics*, vol. 29, October, pp. 589-597. This entire issue of Health Physics is devoted to plutonium.
Shepard, P., and D. McKinley, eds. 1969. *The subversive science*. Houghton Mifflin, Boston. Selected readings in ecology. Excellent, but now somewhat out-of-date.
Shure, D. J. 1971. "Insecticide effects on early succession in an old field ecosystem". *Ecology*, vol. 52, pp. 275-279. The major effect of diazinon on vegetation seems to depend on soil moisture.
Simon, N., and P. Geroudet. 1970. *Last survivors: Natural history of 48 animals in danger of extinction*. World, New York. A handsome volume on some vanishing passengers of Spaceship Earth. Highly recommended.

Singer, S. F., ed. 1975. *The changing global environment*. Reidel, Dordrecht, Netherlands. Interesting collection of papers by the editor and many others, emphasizing climate change and interference in nitrogen cycle (many were written before 1971 and have been only slightly updated).
Singh, H. B.; D. P. Fowler;, and T. O. Peyton. 1976. "Atmospheric carbon tetrachloride: Another man-made pollutant". *Science*, vol. 192, pp. 1231-1234 (June 18). Strong evidence that human activity is the principal source of atmospheric CC14; like the fluorocarbons, a probable precursor of ozone destruction.
Sioli, Harold. 1973. Recent human activities in the Brazilian Amazon region and their ecological effects. In *Tropical forest ecosystems in Africa and South America: A comparative review*, B. J. Meggers, E. S. Ayensu , and W. D. Duckworth, eds. Smithsonian Institution, Washington, D.C. Important source on farming the tropics.
Sladen, W. T. L.; C. M. Menzee; and W. L. Rechel. 1966. "DDT residues in Adélie penguins and a crabeater seal from Antarctica: Ecological implications". *Nature*, vol. 210, pp. 670-673.
Slobodkin, L. B. 1968. "Aspects of the future of ecology". *BioScience*, vol. 18, pp. 16-23. Source on insecticide-brine-shrimp-fish-farming sequence.
Smagorinsky, J. 1974. Global atmospheric modeling and the numerical simulation of climate. In *Weather and climate modification*, W. N. Hess , ed. Wiley, New York.
SMIC. *See*Study of Man's Impact on Climate.
Smith, J. W. 1975. "Spider mites: Population suppression by interspecific hybridization". *Environmental Entomology*, vol. 4, pp. 588-590. Indicates feasibility of using inundations of males of one species to suppress a population of another.

Smith, R. F. 1970. Pesticides: Their use and limitations in pest management. In *Concepts of pest management*, R. C. Rabb and F. E. Guthrie , eds. North Carolina State University Press, Raleigh. General discussion of the problems of pesticide use.
Smith, R. H., and R. C. yon Borstel. 1972. "Genetic control of insect populations". *Science*, vol. 178, pp. 1164-1174 (December 15). An overview with a very useful bibliography.
Smith, W. H. 1974. "Air pollution: Effects on the structure and function of the temperate forest ecosystem". *Environmental Pollution*, vol. 6, pp. 111-129. Review with extensive bibliography.
Snyder, N. F.; H. A. Snyder; J. L. Lincer; and R. T. Reynolds. 1973. "Organochlorines, heavy metals, and the biology of North American Accipiters". *BioScience*, vol. 23, pp. 300-305. Heavy-metal contamination relatively slight and only one, cadmium, positively correlated with eggshell thinning.
Southwood, T. R. E., and M. J. Way. 1970. Ecological background to pest management. In *Concepts of pest management*, R. L. Rabb and F. E. Guthrie , eds. North Carolina State University, Raleigh. An interesting general discussion.
Sparks, R. E.; J. Cairns, Jr.; and A. G. Heath. 1972. "The use of bluegill breathing rates to detect zinc". *Water Raw, arch*, vol. 6, pp. 895-911. A bioassay for a nonlethal toxicant.
Stanford Biology Study Group. 1970. *The destruction of Indochina*. (Reprinted in John P. Holdren and Paul R. Ehrlich, *Global ecology: Readings toward a rational strategy for man*.) On ecocide.
Stanford, G.; C. England; and A. Taylor. 1970. *Fertilizer use and water quality*. United States Department of Agriculture, Washington, D.C., Agricultural Research Service report 41-168. Good overview.
Stockholm International Peace Research Institute (SIPRI). 1976. *Ecological consequences of the second Indochina war*. Almqvist and Wiksell, Stockholm. An excellent, data-rich summary with comprehensive references. This monograph was prepared by Arthur H. Westing.
Stoewsand, G. S., J. L. Anderson, W. H. Gutenmann, C. A. Bache, and D. J. Lisk , 1971. "Eggshell thinning in Japanese quail fed mercuric chloride". *Science*, vol. 173, pp. 1030-1031, 10 September. A suggestive study which, however, does not employ the form of mercury most common in the environment.
Stonier, Tom. 1963. *Nuclear disaster*. Meridian, Cleveland. Describes ecological effects of thermonuclear war; some material outdated by recent ecological work but well worth reading.
Strong, C. L. 1974. "The amateur scientist". *Scientific American*, June. Describes a project in which acid rain was measured throughout the United States by schoolchildren.
"Study of Man's Impact on Climate (SMIC)". 1971. *Inadvertent climate modification*. M.I.T. Press, Cambridge, Mass. Authoritative review, as of 1971, of the potential for human disruption of climate. Excellent bibliography.
Sullivan, A. L., and M. L. Shaffer. 1975. "Biogeography of the megazoo". *Science*, vol. 189, pp. 13-17 (July 4). A discussion of the factors that should be considered in designing a system of wildland reserves to preserve a diversity of plant and animal species as human settlements expand.

SECTION V
The Human Predicament: Finding a Way Out

We have presented a survey of the "hard" sciences associated with the human predicament in the first eleven chapters of this book; the final section considers various aspects of societal response to that predicament. Chapter 12 is relatively brief and transitional. In it are examined the difficult question of how optimum population size might be defined and the ways in which population growth, increasing affluence, and faulty technologies interact to generate environmental impact. The conclusion that all of these causes are inextricably intertwined -- that responsibility for the predicament cannot be ascribed to any one of them in isolation -- provides fundamental background for the chapters that follow. Given this "web of responsibility," how can the world society change its collective behavior in order to permit civilization to persist into the indefinite future? What changes now can assure that in the future people will live reasonably secure and happy lives, supported by properly functioning ecological and social systems?

One step is obvious. The necessity of restraining the growth of the human population has long been evident to thoughtful people. Chapter 13 deals with ways in which this has been attempted in the past, how it might be dealt with in the future, and the current controversy about population control and development. Questions of technology (how effective and safe are contraceptives?), motivation (how can people be persuaded to use contraceptives, sterilization, or abortion?), and morality (should they?) are strongly interconnected. And these issues are not divorced from others equally knotty -- poverty, racial discrimination and political power, to mention a few. While achieving population control rapidly would be very difficult if only for the numerical reasons given in Chapter 5, the difficulty is compounded by various social problems discussed in Chapter 13.

Chapter 14 focuses on American society and its institutions. The United States serves as a model for all developed countries -- the one that in most respects has developed farthest, for better or for worse. If developed countries are to exercise leadership in a revolution of human attitudes and behavior, the most appropriate source for such leadership is the United States. And if such a revolution is to occur, it must involve virtually all parts of the sociopolitical system because of the pervasive nature of the crisis now building. Institutions that help individuals to relate to their environments -- religion, science, medicine, education, and the law -- all are sorely in need of modification to reflect the new realities of existence in the last part of the twentieth century. And the economic and political systems through which individuals have their major impact on the environment require equally drastic revision.

Similarly, as discussed in Chapter 15, the international system as presently constituted offers little hope of resolving the human predicament. A world divided by a vast and widening gap in wealth and income seems even less capable of solving serious problems than is a nation divided into rich and poor -- especially while the poverty-stricken vastly outnumber the wealthy. Some possibilities for reorganizing the world, first to reduce and then to eliminate the gap between rich and poor, is the theme of that chapter. Our conclusion is that the only hope for closing the gap involves changing the ways of life of both the affluent and the hungry. The affluent must recognize that their futures are heavily dependent on the fate of the poor; the poor must accept new goals if their condition is to improve rather than deteriorate.

Ever present in any consideration of the international situation is the threat of nuclear Armageddon. A thermonuclear war is one event that would make almost all the issues and arguments raised in this book academic. Sadly, the probability of such a denouement may well be increasing -- and this adds special urgency to the need for changing the ways in which nations interact.

In Chapter 14 and Chapter 15 especially, we frequently leave the solid ground of facts and venture into the quicksand of opinion and speculation. To do otherwise would be to omit topics that we feel may hold the key to the survival of society. No one can demonstrate "scientifically" that a given modification of the legal system of the United States or of the development goals of Kenya or Brazil will lead to an improvement in the prognosis for humanity, but we do not consider this a valid reason for not discussing such changes. We hope that at the very least our ideas in these and similar areas will stimulate discussion, which in turn may lead to action. For, as should be obvious, we are not sanguine about the prospects for civilization if it continues down its present path.

CHAPTER 12
Humanity at the Crossroads

Maximum welfare, not maximum population, is our human objective.

-- Arnold Toynbee, *Man and hunger*, 1963

The maximum size the human population can attain is determined by the physical capacity of Earth to support people. This capacity, as discussed earlier, is determined by such diverse factors as land area; availability of resources such as energy, minerals, and water; levels of technology; potential for food production; and ability of biological systems to absorb civilization's wastes without breakdowns that would deprive mankind of essential environmental services. Of course, no one knows exactly what the maximum carrying capacity of Earth is; it would certainly vary from time to time in any case. Presumably, the capacity would be sustainable at a very high level for a short period by means of rapid consumption of nonrenewable resources. In the longer term, a lower capacity would be determined by the rate of replenishment of renewable resources and the accomplishments of technology in employing very common materials. Whatever the maximum sustainable human population may be, however, few thoughtful people would argue that the maximum population could be the same as the *optimum*. The maximum implies the barest level of subsistence for all. Unless sheer *quantity* of human beings is seen as the ultimate good, this situation certainly cannot be considered optimal.

The minimum size of the human population, on the other hand, is that of the smallest group that can reproduce itself. Like the maximum, the minimum size is also not the optimum. It would be too small to permit the

many benefits of specialization and division of labor, of economies of scale in the use of technology, of cultural diversity, and so on. The optimum population size, then, lies somewhere between the minimum and maximum possible sizes.

THE OPTIMUM POPULATION

Biochemist H. R. Hulett has made some interesting calculations bearing on the subject of an optimum population. He assumed that the average United States citizen would not consider the resources available to him or her excessive, and he then divided estimates of the world production of those resources by the American per-capita consumption. On this basis, Hulett concluded: ". . . it appears that (about) a billion people is the maximum population supportable by the present agricultural and industrial system of the world at U.S. levels of affluence." [1] By Hulett's criteria, then, even ignoring depletion of nonrenewable resources and environmental deterioration, the population of the Earth is already 3 billion people above the present optimum.

Since decisions that determine population size are made, consciously and unconsciously, by the people alive at a given time, it seems reasonable to define the optimum size in terms of their interests. Accordingly, one might define the optimum as the population size below which well-being per person is increased by further growth and above which well-being per person is decreased by further growth.

Like most definitions of elusive concepts, this one raises more questions than it answers. How is well-being to be measured? How does one deal with the uneven *distribution* of well-being and particularly with the fact that population growth may increase the well-being of some people while decreasing that of others? What if a region is overpopulated in terms of one aspect of well-being but underpopulated in terms of another? What about the well-being of future generations? One cannot define an optimum population for any part of the world at any time without reference to the situation in all other parts of the world and in the future.

No complete answers are possible, but it is time that such questions be seriously addressed. The following observations are intended mainly to stimulate further discussion.

Priorities

The physical necessities -- food, water, clothing, shelter, a healthful environment -- are indispensable ingredients of well-being. A population too large and too poor to be supplied adequately with them has exceeded the optimum, regardless of whatever other aspects of wellbeing might, in theory, be enhanced by further growth. Similarly, a population so large that it can be supplied with physical necessities only by the rapid consumption of nonrenewable resources or by activities that irreversibly degrade the environment has also exceeded the

optimum, for it is reducing Earth's carrying capacity for future generations. If an increase in population decreases the well-being of a substantial number of people in terms of necessities while increasing that of others in terms of luxuries, the population has exceeded the optimum for the existing sociopolitical system. The same is true when population increase leads to a larger *absolute* number of people being denied the necessities -- even if the fraction of the population so denied remains constant (or even shrinks).

It is frequently claimed that the human population is not now above the optimum because if the available food (and other necessities) were in some way equitably distributed there would be enough for everyone. [2] But it is only sensible to evaluate optimum population size in terms of the organisms in the population under consideration, not in terms of hypothetical organisms. Thus, if an area of Africa has more lions than the local prey can support and the lions are starving, then there is an overpopulation of lions even though all the lions could have enough to eat if they evolved the capacity to eat grass.

Grossly unequal distribution of food and other goods is characteristic of contemporary *Homo sapiens* just as

---

[1] Optimum world population. Note that there is a large volume of conventional economic literature in existence that focuses on a narrowly defined economic optimum. This literature is of little interest to the discussion here (see, e.g., Spengler, "Optimum population theory").

[2] For example, Barry "Commoner, How poverty breeds overpopulation" (and not the other way around), *Ramparts*, August/September 1975.

-716- many benefits of specialization and division of labor, of economies of scale in the use of technology, of cultural diversity, and so on. The optimum population size, then, lies somewhere between the minimum and maximum possible sizes.

THE OPTIMUM POPULATION

Biochemist H. R. Hulett has made some interesting calculations bearing on the subject of an optimum population. The same is true when population increase leads to a larger *absolute* number of people being denied the necessities -- even if the fraction of the population so denied remains constant (or even shrinks).

It is frequently claimed that the human population is not now above the optimum because if the available food (and other necessities) were in some way equitably distributed there would be enough for everyone. [2] But it is only sensible to evaluate optimum population size in terms of the organisms in the population under consideration, not in terms of hypothetical organisms. Thus, if an area of Africa has more lions than the local prey can support and the lions are starving, then there is an overpopulation of lions even though all the lions could have enough to eat if they evolved the capacity to eat grass.

Grossly unequal distribution of food and other goods is characteristic of contemporary *Homo sapiens* just as

---

[1] Optimum world population. Note that there is a large volume of conventional economic literature in existence that focuses on a narrowly defined economic optimum. This literature is of little interest to the discussion here (see, e.g., Spengler, "Optimum population theory").

[2] For example, Barry "Commoner, How poverty breeds overpopulation" (and not the other way around), *Ramparts*, August/September 1975.

meat eating is of *Panthera leo*. Cultural evolution might lead toward greater equity (is China showing the way?), and might even produce a species of saints to replace *Homo sapiens* some time in the future. But until that occurs, it would seem wise to consider population optima in terms of human beings as *they now behave* and to strive for a world where everyone has the requisites of life *in spite of* unequal distribution of goods. At the same time, efforts should be made to reduce the inequities, and if they were successful the improved distribution could reduce the degree of overpopulation *without a reduction in population size*.

Density

It is popular among leaders of LDCs to compare their relatively low population densities with the much higher densities of European nations and infer that LDCs can accomodate several times more people per square kilometer than they now have. Population density in itself, however, is a poor measure of overpopulation or underpopulation. [3] Shortages of many resources other than physical space -- for instance, fresh water, fertile soils, suitable climate, or minerals -- may make it difficult to supply even a sparse population in a given area with the necessities of existence. Large parts of Africa, North and South America, and Australia are or could quickly become overpopulated in this respect despite their low densities because over large areas they lack sufficient dependable water, good soils, or a moderate climate.

The suggestion that all land areas can be made to support population densities as great as those of some European countries is misleading for two reasons. First, Europe is blessed with very favorable soils and climate; and second, Europe is by no means self-sufficient, even in food. For instance, Denmark, an exporter of dairy products, eggs, and meat, imports huge quantities of oil-seed cakes and grain to feed its livestock. In the late 1960s, Denmark imported more protein per person than any other country -- 240 pounds per year. This is three times the average annual protein consumption of each Dane!

The favorite example for showing that the world as a whole is underpopulated (averaging 28 people per square kilometer in 1972) is the prosperous Netherlands, which has 326 people per square kilometer. [4] This "Netherlands Fallacy" is an example of what is known in philosophy as the *fallacy of composition* -- that what is true for a part must be true for the whole. The Netherlands can support 326 people per square kilometer only because the rest of the world does not. It ranks second in the world behind Denmark in imports of protein per person, a large portion of which, again, is fed to livestock. Much of the Netherlands' food, most of its fiber, and nearly all the metals needed in industry -- iron, antimony, bauxite, copper, tin, and so on -- are imported. Until the 1970s, when a large natural gas field in the northern part of the country was found and tapped, the Dutch imported nearly half their energy. Now their exports of gas more than compensate for oil imports. [5]

The Netherlands is an extreme example of the general situation of Western Europe. Measured against food demand and production, Europe is already overpopulated. In addition, the continent is a consumer of nonrenewable resources that are largely imported from other areas, and it also has serious population-related environmental problems.

Regardless of the great differences in population densities and degrees of over or underpopulation among nations, it is clear that discussion of population problems must focus on the Earth as a whole, because it has become a single, closed-loop feedback system as far as human activities are concerned. Air pollution is a global problem, resource depletion is a global problem, food shortage is a global problem, chlorinated hydrocarbon pollution is a global problem; thus an excessive population in one area of the world creates problems for all other areas.

Human Values

The concept of an optimum population size must also account for human values beyond physical necessities and economic purchasing power. Such values include an environment that is psychologically as well as physio-

---

[3]For an excellent discussion, see A. T. Day and L. H. Day, "Crossnational comparison of population density".

[4]Figures from the United Nations' *Statistical Yearbook* for 1973.

logically agreeable, a satisfying degree of contact with other people, a variety of educational opportunities, freedom from crime and excessive external restraints on personal behavior, and access to means of resolving conflicts and distributing justice. Many questions can be raised concerning these aspects of the human environment. What degree of contact is satisfying and what amount of interference excessive? How important is solitude for psychological well-being? There is little experimental evidence on most of these questions and little consensus among cultures or even within some cultures on what constitutes an agreeable environment. These uncertainties and lack of consensus suggest that a population size can be considered optimum only if it is far enough below physical limits to permit a good deal of environmental, social, and cultural diversity. Near the limits, diversity must be sacrificed in order to maximize production of physical necessities. As has been discussed in several earlier chapters, productivity and diversity may also conflict in agricultural and other biological systems. More generally, as soon as population growth begins to close more options that it opens, one can say that the population size has exceeded the optimum.

In today's world, many "way of life" options are being rapidly foreclosed. One of the major social consequences of the population explosion -- the seductive technology of the West and the resource exploitation and neocolonialism it has helped to engender -- is what might be described as a decay of cultural variability. Under the pressure of agricultural and tourist development, the ancient way of life of the Hawaiians is rapidly disappearing. It is now difficult to see a genuine hula in the 50th state, and the Hawaiian language is dying out. In Alaska the Eskimo culture has crumpled under the attraction of jobs on the DEW line (Distant Early Warning radar net) and in oil exploration and development. Snowmobiles are replacing dogsleds and old skills and customs are fast disappearing. At opposite ends of the world, the bucolic lifestyles of the Scottish Islanders and the Falkland Islanders are being threatened by oil development. The Indians of

Paraguay are being systematically exterminated to make way for "progress." [6] Indian tribes in the Amazon Basin are being pushed aside or killed in conflicts over territory and food supplies, again for the sake of progress. [7]

The last nomadic human cultures are almost gone. The Tuaregs were all but destroyed by the Sahelian drought; the American plains Indians have long since been herded into reservations. Even in the absence of land-grabbing and other economic motivation, nomadism is dying. Less than 1000 of the 30,000 !Kung bushmen are still nomadic; the rest have settled down as poor farmers adjacent to Bantu settlements, where their nomadic culture is quickly forgotten. Births are no longer widely spaced, and the bushmen consequently are having a population explosion. Women are losing their once nearly equal status with the men because they are no longer major providers and because the Bantus refuse to deal with them. And their children are becoming aggressive, a trait almost completely suppressed among the nomadic bushmen. [8] Similarly, all but a few of the nomadic Australian aborigines are now settled, and their fabled bark paintings are losing their power as they are bowdlerized for trade. Soon this ancient art form may disappear altogether as the old male artists die off and young men refuse to continue the tradition.

The reasons for the conversion of the bushmen and aborigines to a sedentary life are complex, but one factor certainly is the difficulty that governments have in controlling nomads. In Australia, a significant element has been the desire of various missionary groups to control the lives of the nomads and replace their symbol-rich, naturalistic mythology with a considerably duller one of Western invention.

Certain values may be inconsistent with large numbers of people, although numbers themselves may be considered a value by such people as businessmen (who see bigger markets), politicians (who see more political power), or those who want large families. People who promote quantity of human beings as a value in itself, however, may be overlooking the cheapness such abundance often brings. One form of the conflict between values and numbers arises in the choice between having many children who are deprived or having fewer who can

be raised with the best care, education, and opportunity for successful adulthood. The dilemma applies to a society as well as to a family. It is apparently no accident that a disproportionate number of the most successful individuals are first or only children; nor that children of large families (particularly with more than four children), whatever their economic status, on the average perform less well in school and show lower I.Q. scores than their peers from small families. [9]

Although human beings are capable of adapting themselves to a wide variety of environments, it is plain that they do much better in some sets of circumstances than others. A vitally important point is how success of a society is measured -- whether by the number of individuals who can barely survive in a given area, or by the number who can live healthy, productive, reasonably happy, and comfortable lives.

The Time Factor

The optimum population concept is of course a dynamic quantity, not a static one, and the concepts of overpopulation and underpopulation, therefore, are also dynamic. With the passage of time, both technological change and cultural evolution will inevitably change what would be regarded as optimum population sizes. In the face of such changing conditions, the world's governments should be ready to encourage appropriate population trends, just as they now attempt to produce desired economic trends. While the size of the human population must be brought under rational control, it should not be done with the idea of establishing and conforming to some permanently frozen "optimum" number.

In facing the prospects for the near future, it must be remembered that optimum means "optimum under existing social and technological conditions." As indicated above, to argue that a region is not overpopulated by pointing out that certain *hypothetical* social and technological changes might relieve the stresses is to misunderstand the biological meaning of overpopulation. In this context, the conclusion is inescapable that, in terms of present patterns of human behavior and the current level of technology, *the planet Earth as a whole is overpopulated*.

UNDERSTANDING THE WEB OF RESPONSIBILITY: THE FIRST STEP TO SOLUTIONS

Pressures related to the size of the human population are already large and are growing rapidly. There is pressure on physical resources -- land, food, water, forests, metals. There is pressure on the biological environment, whose ability to remove and recycle human wastes and to provide other vital services, from pest control to fish production, is being sorely taxed. There is pressure on society's ability to dispense services -- education, medical care, the administration of justice. Indeed, there is even pressure on such important values as privacy, freedom from restrictive regulations, and the opportunity to choose from a variety of life styles.

Population size is not the only cause of these pressures. The consumption of materials and energy per person are also important factors. So is the type of technology that people employ to make the consumption possible, as well as the economic, political, and social forces that influence personal and institutional decision making. Can these factors be disentangled? Can one or another be identified as the dominant culprit in creating the present human predicament? It would be convenient if the answer were yes, for this would imply that a simple-minded, singlefaceted solution exists.

Unfortunately, the answer is no. All the factors are important, and often they are inextricably linked by an array of cause-and-effect connections. Humanity's predicament has deepened so rapidly because a number of the contributing factors -- population, consumption per person, the

careless use of technology -- *have been growing simultaneously*, and the ability of individuals and governments to adapt their behavior to ever more rapidly changing conditions and problems has not kept pace. Obviously, in considering the causes of humanity's

[9]R. B. Zajonc, "Family configuration and intelligence"; William D. Altus, "Birth order and its sequelac"; L. Belmont and F. A. Marolla, "Birth order, family size, and intelligence". See also Roger Revelle et al., *Rapid population growth; Consequences and policy implications*. It includes several articles on the advantages to children of being first born or in small families.

plight, one is confronted not by a single culprit but by a complex and tightly woven web of responsibility. If human society is to find adequate and rational solutions, it is essential to investigate all the factors that interact to cause these problems and to discover the nature and consequences of the interactions. Although some of the more subjective aspects of the human predicament, such as pressures on values, are perhaps equally important, the problems of resources and the environment are easier to describe quantitatively. We shall therefore use these latter problems to illustrate in more detail what we mean by a "web of responsibility."

Multiplicative Factors

The most fundamental point is that the factors that contribute to growing resource consumption and environmental degradation are multiplicative rather than additive. This idea is expressed by a simple equation,

resource consumption = population × consumption per person, (1)

and by the slightly more complicated one, environmental impact = population

× consumption of goods per person

× environmental impact per quantity of goods consumed. (2)

Since consumption of goods per person is a measure of affluence, and since environmental impact per unit of goods consumed depends on the technologies of production, Equation 2 has sometimes been abbreviated as "impact equals population times affluence times technology." Note also that there is a distinction between consumption of resources and consumption of goods. Producing a good such as food may require large or small amounts of a resource such as phosphate fertilizer, depending on the form of agricultural technology being employed.

For problems described by multiplicative relations like Equations 1 and 2, no factor can be considered unimportant. The consequences of the growth of each factor are amplified in proportion to the size and the rate of growth of each of the others. Rising consumption per person has greater impact in a large population than in a small one -- and greater impact in a growing population than in a stationary one. A given environmentally disruptive technology, such as the gasoline-powered automobile, is more damaging in a large, rich population (many people own

cars and drive them often) than in a small, poor one (few people own cars and drive them less). A given level of total consumption (population times consumption per person) is more damaging if it is provided by means of a disruptive technology, such as persistent pesticides, than if provided by means of a relatively nondisruptive one, such as integrated pest control.

Quantitatively, the important point about Equations 1 and 2 is that slowly growing factors, when they multiply each other, lead to rapidly growing totals. Consider the following example for the resource equation. Suppose we wish to know whether population growth or rising consumption per capita played a greater role in the growth of total energy consumption in the United States between 1880 and 1966. In this period, total energy consumption increased about twelvefold, and the population increased fourfold. [10] It may therefore appear that consumption per capita was a more important factor than population growth. It was not. Consumption per capita increased threefold, versus fourfold for population. The twelvefold increase in the total consumption of energy arose as the *product*, not the sum, of the fourfold increase in population and the threefold increase in consumption per capita.

The results may be even more deceptive when there are three contributing factors, as there are in the environment equation. In a hypothetical case where population, per capita consumption of some commodity, and the impact of technology per unit of consumption all increase threefold, the total impact increases *27-fold*. The contributing factors here are equally important, but each seems quite small compared to the total.

Needless to say, the numerical quantities in the

[10] These and most other statistics in Chapter 12 are from *Historical statistics of the United States, colonial times to 1957*, U.S. Dept. of Commerce, U.S. Gov't Printing Office, 1957; and *Statistical abstract of the United States, 1976*, U.S. Dept. of Commerce, U.S. Gov't Printing Office, 1976.

resource and environment equations will vary greatly depending on the problem under scrutiny. For example, there are many different kinds of environmental impact, and different forms of consumption and technology are relevant to each. The population factor itself may refer to the population of a city, a region, a country, or the world, depending on the problem being considered. Our formulas, then, represent not just two calculations but many. We shall give a number of examples below--but first a few comments about the individual factors are in order.

Population. The U.S. and world population situations have already been discussed in detail in Chapter 5. For the purposes of elucidating the role of population growth and the other factors in the web of blame, we shall focus on the United States over various time periods in the span from 1900 to 1975. The total population and urban population of the United States for several years in this period are given in Table 12-1. The table shows that the U.S. population in 1970 was 2.7 times as large as in 1900 and 1.55 times as large as in 1940. The urban population has increased even faster: in 1970 it was 4.95 times as large as in 1900 and 2 times as large as in 1940.

Affluence and consumption. How does one measure affluence? This is certainly a more difficult task than counting people. A conventional but much criticized measure of affluence is Gross National Product per capita. Gross National Product (GNP) consists of expenditures by consumers and government for goods and services, plus investment. So that figures for different years can be meaningfully compared in spite of inflation, they are usually converted to their equivalent in the dollars of some reference year. GNP per capita in the United States, measured in 1958 dollars, is given for selected years between 1900 and 1975 in Table 12-2. GNP per person, corrected for inflation, was 4.06 times as large in 1975 as in 1900 and 2.2 times as large as in 1940.

As is detailed in Chapter 14, it is easy to find fault with GNP as a meaningful index of affluence. In one sense it includes too much. Dollars spent on catching and prosecuting a growing number of violators of a growing

TABLE 12-1
United States Total and Urban Population in Selected Years

Year	Total population	Urban population
1900	76,094,000	30,160,000
1910	92,407,000	41,999,000
1940	132,122,000	74,424,000
1946	141,389,000	--
1968	201,177,000	--
1970	205,200,000	149,279,000
1975	213,540,000	--

number of laws contribute to GNP, as do the costs of wars and the costs of attempts to clean up pollution. Since these expenditures reflect or are necessitated by a declining rather than an improving quality of life, they should hardly be regarded as an indication of affluence. In another sense, GNP takes too little into account. Perhaps the "cost" of decaying cities, now being paid not in dollars but in the misery of those who must live and work there, should somehow be *subtracted* from GNP.

Despite the shortcomings of GNP as a measure of affluence, no alternative measures have yet gained wide acceptance. One possible approach is to use production or consumption of certain basic materials as an indicator. Typically, steel and energy are chosen as representative commodities, simply because large quantities of both are essential to running an industrial civilization. Another critical material in this connection is water. Figures for steel, energy, and water are given in Table 12-3. Note

TABLE 12-4
Stock of Consumer Durables in the United States

Item	1940s	1970s
Automobiles in use per capita	0.21 in 1940	0.59 in 1973
Refrigerators in use per capita	0. 15 in 1946	0.27 in 1973
Clothes dryers in use per capita	0.001 in 1949	0.16 in 1973
Percentage of households with air conditioners	0.2% in 1948	48.6% in 1973

that the per capita use or production of these commodities in the United States has increased between twofold and fourfold since 1900. The figures are not entirely unrelated, of course. It takes water and energy to produce steel; steel and water to make energy available; steel and energy to make water available.

Using flows of materials as an index of affluence has the drawback that it is often not *flow* that measures well-being but rather the stock of goods maintained by the flow. Owning a refrigerator is an indication of affluence; having to replace it frequently is not. Thus the amount of steel or the number of refrigerators and automobiles in existence in a society are better measures of affluence than the annual consumption or sales of these things. The quantity of goods, machinery, and materials owned or in existence is often referred to as *capital stock*; the annual consumption, or *throughput* as it is sometimes called, measures additions to the stock itself and replacement of losses (for example, junked automobiles that are not reclaimed). To the extent that a part of GNP is just flows of goods and materials measured in dollars, GNP shares the defect of focusing on throughput rather than on capital stock.

Changes over the last few decades in the capital stock of a number of goods known as *consumer durables* are shown in Table 12-4. Such figures are rather good indicators of rising affluence.

In some instances, of course, a flow rather than a stock is the appropriate measure of affluence. This seems to be the case for the necessities of existence--food, clothing, and shelter. In the case of food, kilocalories and grams of protein per day measure adequacy; beyond that, annual dollar expenditures on food measure variety and quality. To some extent, rising expenditures on food may also reflect increasing costs of production (to be discussed below). On the average, diets have been adequate in terms of quantity in the United States throughout this century. But increasing affluence, as reflected in expenditures on food, is very apparent in Table 12-5. Since

clothing wears out rather rapidly, annual expenditure (a flow) is a reasonable measure of the quality of the stock. In the case of shelter, annual per capita expenditure in the form of rent or mortgage payments is probably a reasonable index of quality, after correction has been made for inflation. Statistics like "housing units" per capita do not help much; they measure the size of living groups, but they do not distinguish between one-room apartments and palatial mansions. Clothing and housing expenditures are shown along with those for food in Table 12-5.

Obviously, there are many ways to define and measure affluence, none of them completely satisfactory. Nevertheless, the picture that emerges from all the admittedly imperfect measures is a consistent one: affluence, by any reasonable definition, has increased dramatically in the United States in this century and especially in the last 30 years.

Technology. As noted above, society's emphasis on throughput in economic accounting sometimes leads to oversimplifying the connection between consumption and affluence. The factor most responsible for the real complexity of this connection is the character of the technology used to transform flows into benefits.

The relations among consumption, affluence, and

technology are well illustrated by the example of energy. Some of our energy consumption provides direct benefits in the form of heat for cooking and for heating water and space (homes, offices, etc.). Even in space heating, however, the real benefit is the "stock" of heat maintained inside, and the flow of energy is needed only to replace losses through walls, windows, and so on. The amount of energy flow needed to maintain a given temperature depends on technology, particularly the efficiency with which fuel is converted to heat and the quality of the insulation in the buildings being heated.Another substantial part of society's energy consumption is needed simply to make possible the large throughput of other materials in our economy--steel, water, glass, plastics, and paper, to name some important ones. For given rates of consumption of these materials, the amount of energy required again depends on the technology used: the details of mechanical and chemical processing; whether or not recycling is employed; whether the process uses electricity or direct combustion of fuel; and so on. Transportation is yet another component of affluence in which energy consumption depends strongly on the sort of technology employed--small cars or large ones, trains or planes, gasoline engines or electric motors, and so on.Technology is constantly changing. Such changes are stimulated largely by economic factors, such as the desirability of cheaper methods of production of existing kinds of goods; the profitability of inventing and marketing new kinds of goods; and the need to find substitutes for materials made scarce by heavy demands. Partly because ecological values have not been properly accounted for in our economic system, the changes in technology stimulated by that system have sometimes been profoundly disruptive of the environment.The rapidly rising reliance on plastics in American manufacturing is a technological change that can be attributed partly to the quest for cheapness, partly to the desire for durability (which is admirable as long as the plastic is not being used in throwaway goods), and perhaps partly to scarcity of alternate materials such as certain kinds of wood. Of course, if the economic system is functioning "properly," scarcity leads to rising prices, so the cheapness of plastic and scarcity of the alternative reinforce each other.Increasingly heavy use of fertilizers and synthetic organic

pesticides in agriculture is a technological change stimulated partly by increased total demand for food and partly by economic forces that dictate *how* a greater demand will be met. In this case, alternatives would have been to bring more land into production, to promote labor-intensive rather than capital-intensive, high-yield agriculture, or to use integrated pest control.**Environmental impact.** Only in a relatively few cases is it easy to assign an exact numerical value to the third factor in Equation 2--the environmental impact associated with a particular amount of consumption. It is possible to record the emissions of lead and oxides of nitrogen per vehicle mile, the pounds of sulfur dioxide released per kilowatt-hour of electricity generated, and other similar data. Even when such numbers are available, however, really good analysis is made difficult by several factors:

Most forms of consumption give rise to many different forms of environmental impact. For example, electricity production from coal causes air pollution, water pollution, solid waste, defacement of the landscape, and disruption of local ecosystems. Changes in technology may reduce some aspects of impact while increasing others.

The different kinds of impact associated with alternative technologies to meet the same need are hard to compare. For example, how does one compare the environmental impact of oil spills with that of coal mining?

Most of our knowledge concerns what people put into the environment, but not how the environment responds. This accounts for much of the difficulty associated with the previous two points. It is not enough to know how much lead is emitted by human activities; it is necessary to know how to put numerical values on the human health effects in the short and long term, on any impairment in the functioning of individual species of plants and animals, and on the general ecological effects resulting from the simultaneous action of lead on many organisms at once. It is not enough to know how much nitrogen is applied to fields; it is also necessary to know in detail what the health effects and ecological effects are

after it gets there. In short, it is *response*, not *input*, that really defines environmental impact. In almost every case, society's knowledge is far from adequate to assess this response quantitatively.

All this is not to say that society is too ignorant to take corrective action. The evidence of damage is overwhelming, and many of the basic causes are clear. But one must be cautious about using selected numbers to draw sweeping conclusions about the numerical increase in environmental damage over a given time span, and about the assignment of responsibility among the many factors that play a role.

The United States Since World War II

The pitfalls of underestimating the complexity of the web of responsibility are well illustrated by the statement frequently heard that "faulty technology" developed since World War II has been the principal culprit generating the environmental crisis in the United States. [11] Examination of this hypothesis is a useful way to look more deeply and specifically into some of the points raised above.The main evidence offered to show that technology has been the dominant environmental villain is the observation that some indices of pollution in the United States have increased by 200 percent or more since World War II, while the population and affluence were growing much more slowly. Among the usual examples of dramatically increasing sources of pollution in the postwar period are emissions of lead and nitrogen oxides in auto exhausts, the use of synthetic pesticides and nitrogen fertilizer in agriculture, and the use of phosphates in

detergents. But these examples would support the hypothesis only if *all* of the following conditions were met:

1. The calculations for these examples showed that population growth and rising affluence have been minor contributors to the total increase, arithmetically speaking.
2. The changes in technology that led to rapid growth in these indices of pollution were not sometimes *caused* by increases in total demand (population times consumption per capita) that could not be met by earlier technology.
3. The examples represented a valid sampling of all important kinds of environmental impact.

In actuality, *none* of these conditions is met by examples that have been said to demonstrate a dominant role for faulty technology.

Arithmetic of growth. Because the contributing Factors--population growth, per capita consumption, and technology--are multiplicative, each factor is important no matter how fast the other factors have grown. According to Table 12-1, the U.S. population grew 45 percent between 1946 and 1970. In purely arithmetic terms (ignoring all possible cause-and-effect connections between population growth and the other factors), this says that our impact would only have been about two-thirds as large in 1970 as it actually was if the population had not grown in this interval. (The ratio of the 1946 population to that in 1970 is 1/1.45 = 0.69, or slightly over two-thirds). Of the large total increase in impact, the one-third that is "explained" by population growth is an important contribution.

Table 12-2 shows that by one measure, GNP per person corrected for inflation, affluence grew 57 percent between 1946 and 1970. If GNP per capita were in fact a valid measure of the contribution of affluence to environmental impact, these figures would indicate that the 1970 impact would have been only 64 percent as large as it actually was if affluence had not grown in the 19461970 interval, again ignoring cause-and-effect connections among the factors. (The ratio of the 1946 per capita GNP to that in 1970 is 1/1.57 = 0.64.) If neither population nor affluence had grown since World War II, the total environmental impact in 1970 would have been only 44 percent (.69 x .64) of that actually experienced (within the limitations of GNP per person as a measure of the contribution of affluence to environmental impact, and ignoring cause-and-effect connections among the factors).

---

[11] The most vigorous exponent of the "faulty technology" hypothesis has been biologist Barry Commoner, whose book *The Closing Circle* contains a number of the specific fallacies we describe in this chapter.

BOX 12-1 Automotive Lead: A Case Study

The emissions of lead from automobile exhausts increased 415 percent in the period between 1946 and 1968. Does this mean that the 42 percent increase in the population was responsible for only one-tenth of the increase in emissions? Not at all, because the contributing factors are multiplicative, not additive. Let us rewrite the equation given in the text symbolically (using as a

multiplication sign): $I = P \cdot C \cdot T$, where I denotes environmental impact, P is population, C is consumption per person, and T is the technological impact per unit of consumption. If, in a given time period, the increases in the various quantities are denoted ΔI, ΔP, ΔC, and ΔT, then the equation for the later time is $I + \Delta I = (P + \Delta P) \cdot (C + \Delta C) \cdot (T + \Delta T)$.

Percentages emerge when the equation is re-written in the form

$$1 + \frac{\Delta I}{I} = \left(1 + \frac{\Delta P}{P}\right) \cdot \left(1 + \frac{\Delta C}{C}\right) \cdot \left(1 + \frac{\Delta T}{T}\right)$$

where $\Delta I/I$ times 100 is the percentage increase in environmental impact, $\Delta P/P$ times 100 is the percentage increase in population, and so on. (Note that an increase of 100 percent means a doubling of the initial quantity, an increase of 200 percent a tripling, and so on.)

The 42 percent increase in population between 1946 and 1968 means that $\Delta P/P$ for this period is 0.42 and the population factor, $I + \Delta P/P$, is 1.42. In considering automotive emissions, the quantity "consumed" is vehicle miles per capita, which doubled in the period in question. Thus $\Delta C/C = 1.00$, $1 + \Delta C/C = 2.00$. The complete impact equation for lead emissions from automobiles therefore is

$$\begin{aligned} 1 + \frac{\Delta I}{I} &= 1 + 4.15 = 5.15 \\ &= \left(1 + \frac{\Delta P}{P}\right) \cdot \left(1 + \frac{\Delta C}{C}\right) \cdot \left(1 + \frac{\Delta T}{T}\right) \\ &= 1.42 \cdot 2.00 \cdot 1.81 \end{aligned}$$

In this example, the technology factor, emissions of lead per vehicle mile, is intermediate in importance between the population factor and the consumption factor. Population is not unimportant (without population growth, the total increase would have been 262 percent rather than 415 percent); technology is not dominant. This is so even though the emission of lead by automobiles is one of the *best* available examples of faulty technology in the post-war period.

The point here is not that the relative impact of technology has not grown substantially since World War II; in some cases, it has. But *especially* in such cases the total impact has been made that much greater because population and affluence were growing too. Some arithmetic

calculations pertaining to growing environmental impact are shown in full detail in Box 12-1, using the actual example of automotive lead emissions since World War II.

Cause-and-Effect Relations

Increases in total consumption, brought about by population growth and rising affluence, can cause changes in the technology factor in several ways. Consider the use of man-made fibers such as nylon in clothing. The rapidly growing synthetic fiber industry is often cited as an example of an ecologically faulty technology, since these materials require large quantities of energy in their production and degrade only slowly in the biosphere. However, providing today's total U.S. demand for fiber *without* the synthetics would have required nearly a doubling in production of cotton and wool by 1972 over the 1945 levels (which were higher than some more recent ones). Whether this would have been practical at all is questionable. And, if it had been done, what would have been the ecological costs in terms of pounds of fertilizer and pesticides applied to cotton fields, the side effects of irrigation projects, and the erosion of farmland resulting from overgrazing? What about the loss of acreage to food production given over to

cotton and flax? Clearly, technology changes with demand, and it is meaningless to consider the environmental and economic impacts of one kind of technology without also considering the impacts of alternative technologies that would permit the same material consumption.

Aluminum is another material whose consumption is increasing rapidly and which requires a great deal of energy to obtain from ore. Its use in cans is certainly a faulty technology unrelated to population growth or real affluence, but containers comprise only 10 percent of U.S. aluminum use. Fourteen percent is used in the electrical industry, where aluminum has been substituted for copper, which has been made scarce by heavy demands. Twenty-two percent is used in building and construction, partly to replace wood in siding, window frames, awnings, and so on. Nineteen percent is used in the manufacture of vehicles--automobiles, trucks, aircraft--where its light weight in comparison to alternative metals leads to substantial fuel energy savings in operation. [12] Meeting the demands of a growing population for better housing with wood alone would put additional pressure on forests, some of which are already being too intensely exploited. Substitutions of one material for another--nylon for cotton, aluminum for copper, aluminum and plastics for wood--are inevitable as a growing, increasingly affluent population presses on a finite resource base. Obviously, any additional environmental impact that results from such substitutions cannot justifiably be blamed on "faulty technology" alone.

Another way in which population growth and rising per capita consumption cause increases in technological impact is through the *law of diminishing returns*. This refers to a situation in which, in the jargon of the economist, the additional output resulting from each additional unit of input becomes less and less. Here "output" refers to a desired good (such as a food or metal), and "input" refers to what must be supplied (say, fertilizer, or energy, or raw ore) to obtain the output. Suppose that consumption of goods per person is to be held constant while the population increases. If the law of diminishing returns prevails, the per-capita consumption of inputs needed to provide the fixed per-capita level of goods will increase. Since environmental impact is

generated by the inputs (such as energy) as well as by the use and disposal of the goods themselves, the per-capita impact will also increase.

To see how the law of diminishing returns operates in a specific example, consider the problem of providing nonrenewable resources such as minerals and fossil fuels to a growing population, even at unchanging levels of per-capita consumption. More people means more demand, and thus more rapid depletion of resources. As the richest supplies of these resources and those nearest to centers of use are consumed, it becomes necessary to use lower-grade ores, to drill deeper, and to extend supply networks. All these activities increase the *per capita* use of energy and hence the *per capita* impact on the environment. In the case of partly renewable resources such as water (which is effectively nonrenewable when groundwater supplies are mined at rates far exceeding natural replenishment), per-capita costs and environmental impact escalate enormously when the human population demands more than is locally available. Here the loss of free-flowing rivers and other economic, aesthetic, and ecological costs of massive watermovement projects represent increased per-capita penalties directly connected to population growth. Of course, these effects would also eventually overtake a stationary population that demands more than the environment can supply on a perpetual basis; growth simply speeds up the process and allows less time to deal with the problems created.

The law of diminishing returns is also at work when society tries to increase food production to meet the needs of growing populations. Typically, attempts are made both to overproduce on land already farmed and to extend agriculture to marginal land. Overproduction requires increased energy use out of proportion to the gain in yield, through the processes of obtaining and distributing water, fertilizer, and pesticides. Farming marginal land also increases per-capita energy use, since the amount of energy invested per unit of yield increases as less desirable land is cultivated. Both activities often "consume" the fertility built into the natural soil structure. Similarly, as the richest fisheries stocks are depleted, the yield per unit of effort drops, and more and more

[12]Figures on aluminum use are from National Commission on Materials Policy, *Material Needs and the Environment Today and Tomorrow*, (Government Printing Office, Washington, D.C., 1974.

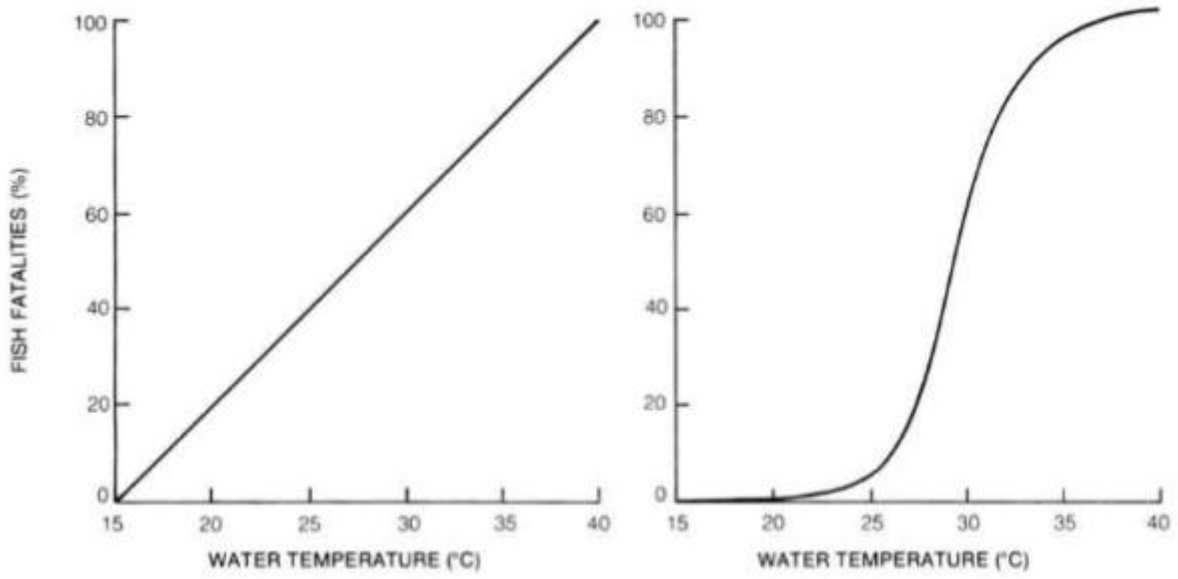

FIGURE 12-1 Idealized linear and nonlinear dose-response relations. In the real world, graphs like that on the right usually apply.

energy per capita is required to maintain the supply. Once a stock is depleted beyond a certain point it may not recover--it may be effectively nonrenewable.

Substitutions and diminishing returns are examples of the way in which population growth and rising consumption generate disproportionate increases in the *input* side of environmental impact--in what mankind *does to* the environment. Mankind's environmental predicament is also greatly aggravated by situations where relatively small changes in inputs may cause dramatic changes in the environment's *response*.

Threshold effects are one such type of situation. For example, below a certain level of pollution, trees will survive in smog. But when a small increment in the local human population produces a small increment in smog, living trees become dead trees. Perhaps 500 people can live around a certain lake and dump their raw sewage into it, and its natural systems will be able to break down the sewage and keep the lake from undergoing rapid ecological change. But 505 people may overload the system and result in a polluted or eutrophic lake.

Such thresholds characterize the responses of many organisms or groups of organisms to many different kinds of environmental changes: fish die when water temperature exceeds a certain threshold or when dissolved oxygen content falls below a certain threshold; different crops have different thresholds for tolerance of dissolved salts in irrigation water; carbon monoxide is fatal to people at high concentrations, but, as far as is known, causes only reversible effects at low concentrations. Scientists describe such situations as displaying a *nonlinear dose-response relation*. Nonlinear in this context means that a graph plotting response (say, percentage of deaths in a population of fish) versus dose (say, temperature in the habitat) will not be a straight line. The difference between linear and nonlinear dose-response relations is shown schematically in Figure 12-1.

Another form of nonlinear behavior in dose-response relationships is *synergism*. Here one is concerned with the simultaneous interacting effects of two or more kinds of input, where each kind of input acts to intensify the effects of others. For example, sulfur dioxide and various kinds of particulate matter are found at the same time in city air and for hundreds of miles downwind, and the combination appears to cause measurable adverse effects on health when the concentrations of both pollutants are well below the levels where one is dangerous individually. [12a] (One possible explanation is that sulfur dioxide adsorbed onto fine particles penetrates further into the lungs than the pure gas can; another is that the particles accelerate the transformation of sulfur dioxide into more dangerous sulfates.) Thus the joint effect is *synergistic*: it exceeds the sum of the individual effects expected if sulfur dioxide and particles had been present separately.

Synergisms also occur in environmental systems that

[12a] See, for example, David A. Lynn, *Air pollution*, Addison-Wesley, Reading, Mass., 1976, p. 97, and Chapter 10 here.

influence human health less directly than the incidence of disease. A particularly disturbing example is the combined effect of DDT and oil spills in coastal waters. DDT is not very soluble in sea water, so the concentrations to which marine organisms are ordinarily exposed are small. However, DDT is very soluble in oil. Oil spills therefore have the effect of concentrating DDT in the surface layer of the ocean, where much of the oil remains, and where many marine organisms spend part of their time. These organisms are thus exposed to far higher concentrations of DDT than would otherwise be possible. As a result, the combined effects of oil and DDT probably far exceed the individual effects. [12b] Many other synergisms in environmental systems are possible. Investigation of such effects is one of the most difficult (and neglected) areas of environmental analysis.

Other forms of impact. It is possible to get the impression from some of today's discussions of environmental problems that society's troubles began with the advent of the internal combustion engine, DDT, and nuclear fission. Although these are significant problems, we have shown in previous chapters that they are far from the whole story. Loss of good land to erosion, to faulty irrigation practices, and to overgrazing dates back thousands of years. [12c] Scattered over Earth are the remains of past ecocatastrophes, from Angkor Wat to the Tigris and Euphrates valleys to deforested southern Europe and the Middle East. Serious environmental deterioration was caused and is still being caused by preindustrial societies--especially by their agricultural practices. [13] The southward spread of the Sahara and contributions of dust to atmospheric pollution made by subsistence farmers are cases in point.

In addition, overexploitation of commercially valuable species of plants and animals has driven some to extinction and threatens many others--whales, a dozen species of fishes, several kinds of wild cats, birds, hardwood trees, and so on. Ocean fisheries are threatened by destruction of breeding grounds through dredging and filling operations in estuaries and marshes, as well as by overfishing and pollution. The extension of monocultures of a few, selected high-yield varieties of grain over large areas is increasing the vulnerability of world agriculture to disruption. In the

United States, some of the best agricultural land is continually disappearing under suburbs, airports and highways. In short, there is a great deal more to environmental deterioration than pollution.

No single index can measure these numerous forms of environmental impact. For many of them, even statistics are lacking from which some allocation of responsibility among population growth and the other contributing factors could be derived. Many observers agree, however, that use of energy is the best single measure available of human impact on natural surroundings. The use of energy is central to most of the activities in question, and it is a direct contributor to many of the most obvious environmental problems. [13a] Moreover, as noted above, energy consumption per capita combines within a single statistic a measure both of affluence and of the impact of the technology that provides the affluence. It may not be possible to unravel the numerous connections *between* population size and per capita energy consumption. Nevertheless, it is useful to weigh the purely arithmetic contributions of these two factors to the recent growth of *total* energy consumption.

In an earlier example, we showed that population growth was a greater contributor than rising consumption of energy per capita to the increase in total U.S. energy consumption over the past 95 years. During a more recent period, 1940 to 1975, the population increased by 62 percent while energy consumption per capita increased by 83 percent. Worldwide, energy consumption during the 1960s and early 1970s was increasing at about 5 percent per year-about 2 percent per year due to population growth and 3 percent per year due to rising consumption per capita. Obviously, if energy consumption is a good measure of environmental

[13a] Of eleven global environmental problems identified as potentially serious in the landmark Study of Critical Environmental Problems (SCEP, *Man's impact on the global environment*, M.I.T. Press, Cambridge, Mass., 1970), six stem directly from energy production and two more from the use of fuels in high-flying jet aircraft.

impact, population growth has continued to be an important contributor to that impact, both in the United States and in the world as a whole.

Perfect Technologies and Shifting Impact

It is sometimes claimed that dramatic improvements in technology will compensate for continued growth in population and consumption per person. That is, if the per-capita impact on the environment due to technology can be sufficiently reduced, growth in population and consumption per capita need not lead to increased environmental degradation. This is certainly true for some kinds of activites and for a limited time. Some kinds of air pollution in the Los

Angeles Basin, such as hydrocarbons and carbon monoxide, were decreasing in the early 1970s, even though both the population and the consumption of fuels were increasing. Installation of sewage treatment facilities in the late 1960s subsequently improved water quality in Seattle's Lake Washington and Wisconsin's Lake Mendota despite growing populations in these areas.

Such technological improvements should certainly be sought and applied, but they are not complete cures. One reason is that many technological "fixes" for environmental problems simply shift the impact to somewhere else, rather than removing it. Incinerating garbage pollutes the air, and available techniques for removing oxides of sulfur from power plant exhaust gases generate either solid wastes or water pollution. Switching from internal combustion engines to electric automobiles simply shifts part of transportation's pollution burden from the air over highways to air over power plants. Removing the lead from gasoline has apparently increased particulate emissions and may have increased the proportion of emitted hydrocarbons that are carcinogenic as well.

Even the approaches that successfully relieve one problem without creating another one are nevertheless imperfect. There is no such thing as "zero emissions." As percentages of contaminants per unit volume of effluent (say, treated water or stack gases from power plants) are reduced to very small levels, the costs of the control measures in dollars and energy become very large. In fact, reducing contaminant concentrations to zero would require an infinite amount of energy. Long before it could be achieved, of course, the environmental impact associated with supplying the energy for pollution control would exceed the impact of the pollution itself. This is the law of diminishing returns at its worst.

A good example is the economics of sewage treatment. The cost of removing 80 to 90 percent of the biochemical and chemical oxygen demand (standard indices of pollutants in water), 90 percent of the suspended solids, and 60 percent of the resistant organic material by means of secondary treatment in the late 1960s was about 8 cents per thousand gallons in a large plant. But if there is so much sewage that its nutrient content creates a serious eutrophication problem (as is the case in much of the United States today), or if water is in such short supply that sewage water must be reused for industry, agriculture, or ground-water recharge, advanced treatment is necessary. The cost ranges from 2 to 4 times as much as for secondary treatment (17 cents per 1000 gallons for irrigation of food crops, 34 cents per 1000 gallons to yield a drinkable supply). [14] This story could be repeated for many other forms of environmental impact.

There is good reason to believe, therefore, that an increasing fraction of national income will have to be spent during the next few decades to hold pollution to tolerable levels. Even then, some important aspects of the problem may go unnoticed until irreversible damage has been done, and other aspects may worsen for the lack of available technology to deal with them at any price. At the moment, for instance, no technology has been developed to control emissions of nitrogen oxides from electric power plants, and it is not practical to control emissions of carbon dioxide from all combustion of fossil fuels because the volume of the effluent is so great. Tilling the soil and mining operations may accelerate the rate at which mercury is removed from Earth's crust and injected into the ecosystem. [15] More mercury may be released to the environment this way than by industrial processes, and no remedy is known.

As noted in earlier chapters, the ultimate pollutant is

[14]Figures on cost of sewage treatment are from *Cleaning our environment: the chemical basis for action*, Washington D.C., American Chemical Society, 1969.

[15]See K. K. Bertine and E. D. Goldberg, "Fossil fuel combustion and the major sedimentary cycle", *Science*, vol. 173, p. 233, 1971.

heat. All recycling and other forms of pollution control require energy, and all the energy people use ultimately turns up in the environment as waste heat. More efficient generation and utilization of energy can relieve this problem somewhat, but they cannot eliminate it. If, miraculously, all other environmental defects of our technology could be remedied, this one would remain.

It must be concluded that improving technology to reduce its contribution to total environmental impact is worthwhile but is not the entire answer. Under any set of technological conditions, there will be some impact associated with each unit of consumption, and, therefore, at some level of population size and consumption per person, the total impact will become unsustainable.

THE PROSPECTS

The tightly interlocked and simultaneously growing factors that comprise what we have called the web of responsibility must *all* be attacked if humanity is to avoid future environmental breakdowns or mass famines. A strategy that treats only *some* of the factors is bound to fail. The interrelated consequences of various policies have been sharply illustrated by *The Limits to Growth* [16] (sponsored by the Club of Rome and further described in Box 12-2), which suggested that only by controlling all the interacting factors could future catastrophe be averted.

BOX 12-2 Computer Models and the Limits to Growth

The appearance in 1972 of the book *The Limits to Growth* generated an international storm of controversy. The book describes the results of a project carried out at the Massachusetts Institute of Technology on "the predicament of mankind" --the interlocking problems of population, food, raw materials, pollution, and economic growth. The principal conclusions of the project were that the trends characterizing these elements of the human condition in the twentieth century could not be sustained for long into the future, and that if the growth of population, industrial production, and pollution were not stopped by enlightened social action, then they would be stopped by one or more kinds of physical catastrophe -- famine, resource exhaustion, or epidemic disease. Figure 12-2 shows the projected results of present trends if they continue with no interference from society. In addition, the model demonstrated that controlling only one or two of the major interacting influences on the world system -- population, resource depletion, environmental deterioration -- would produce at least equally disastrous results. To take just one example, if a program of reducing demands on exhaustible resources (by finding abundant substitutes, recycling, and so forth) were established without controlling the other factors, the consequences would be worse than a future in which resources were exhausted. To quote Jay W.

Forrester of M.I.T., who published early results of the study in 1971, on the results of a computer run in which it was assumed that technology could circumvent resource limits:

By not running out of resources, population and capital investment are allowed to rise until a pollution crisis is created. Pollution then acts directly to reduce birth rate, increase death rate, and to depress food production. Population, which, according to this sample model, peaks at the year 2030, has fallen to one-sixth of the peak population within an interval of 20 years -- a world-wide catastrophe of a magnitude never before experienced. [a]

Forester's and the Meadows' analyses (and those of subsequent workers such as Mesarovic and Pestel [b]) projected the collective results of various trends in this way, in each case controlling or altering different interacting factors.

[b]M. Mesarovic and E. Pestel, *Mankind at the turning point*.

Their results showed that some form of disaster lies ahead unless *all* the factors are controlled: population growth, pollution, resource consumption, and the rate of capital investment (industrialization).

This was hardly a new conclusion in 1972. Indeed, the argumentation and evidence for this general world-view had been accumulating steadily since the time of Malthus (see Box 13-2), and a rash of books drawing substantially similar conclusions had appeared in the decades following World War II. [c] What accounts, then, for the extraordinary response -- both disparaging and laudatory -- that these views elicited when they appeared in *Limits to Growth* in 1972?

Several factors contributed: first, the status of M.I.T. as virtually a worldwide synonym for careful scientific analysis; second, the sponsorship of the project by the vaguely mysterious Club of Rome, an international collection of influential academicians, industrialists, and public figures; third, the extraordinarily direct and lucid style with which the authors presented their conclusions; and fourth, the major role played in the underlying analysis by a "computer model" of the world.

Of these factors, the last was almost certainly the most important. The book appeared at a time when the capabilities of large computers had already become part of public conventional wisdom (or folklore), but when the idea that computer results are no better than the information fed into them was not so widespread. Thus the notion that a computer had certified the bankruptcy of growth gave the conclusion public credibility, and at the same time provided a target for indignant economists and others who saw the outcome as an illustration of the syndrome known in the computing trade as "garidea behind computer modeling is to simulate in bage in, garbage out." [d]

How do computer models in general, and the Limits model in particular, actually work? The

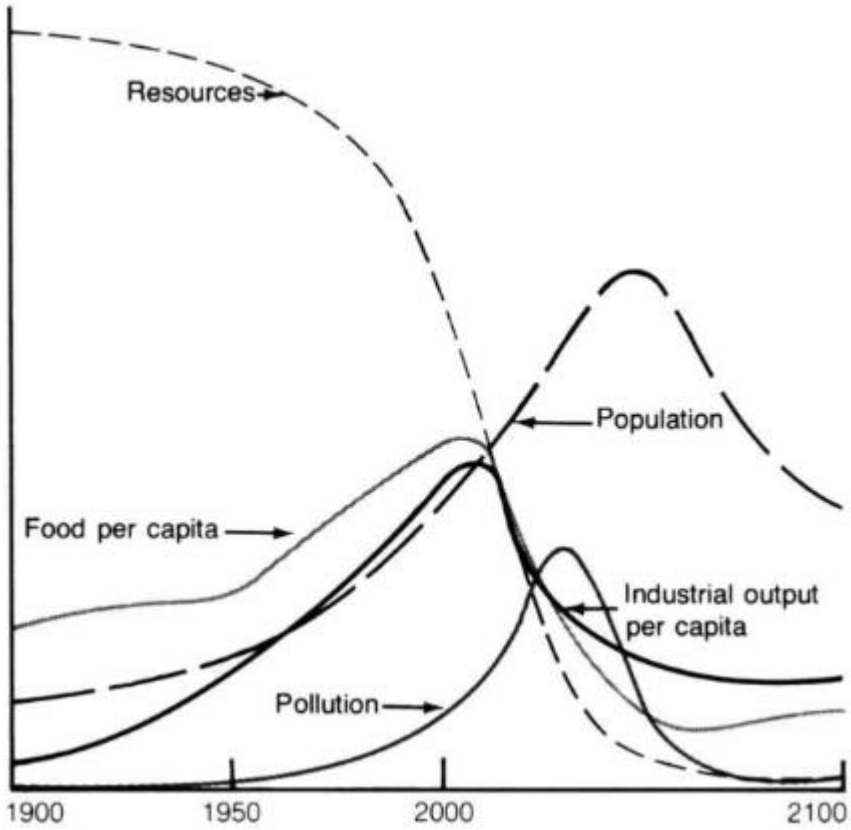

FIGURE 12-2 The "standard" world model run assumes no major change in the physical, economic, or social relationships that have historically governed the development of the world system. All variables plotted here follow historical values from 1900 to 1970. Food, industrial output, and population grow exponentially until the rapidly diminishing resource base forces a slowdown in industrial growth. Because of natural delays in the system, both population and pollution continue to increase for some time after the peak of industrialization. Population growth is finally halted by a rise in the death rate due to decreased food and medical services. (After Meadows et al., 1972.)

idea behind computer modeling is to simulate in a general way the behavior of complicated physical systems. The technique is used when the situation of interest is too complicated to analyze with equations solvable with pencil and paper, or with laboratory or field experiments on a reasonable scale; and when it is too time-consuming or too risky simply to observe the real system and see what happens. Systems or processes that meet these conditions and that accordingly have been studied with computer models include the global meteorological system, various ecosystems, the safety systems of nuclear reactors, the growth of cities, and the evolution of galaxies.

In all such cases, models are constructed by identifying what seem to be the most important

[c]For example, William Vogt, *Road to survival*; Fairfield Osborne , *Our plundered planet*;

H. Freeman, San Francisco, 1969; P. R. Ehrlich and A. H. Ehrlich, *Population resources, environment*, W. H. Freeman, San Francisco, 1970.

[d] See, for example, K. Kaysen, The computer that printed out W*O*L*F, *Foreign Affairs*, 1972, which tries but fails to stick the "garbage" label on *Limits to Growth*, missing the point in major respects.

components of the system under study and by writing down in mathematical form what seem to be the main cause-and-effect relationships linking these components. The components are characterized by the values of associated "state variables"--for example, the surface temperature of the ocean, the pressure in a reactor core, the population of a city. Sometimes the relationships between different variables are known exactly from physical laws, but more often these links must be represented in very approximate or even hypothetical form, consistent with whatever limited data may be available from the "real world."

The computer model used in the *Limits to Growth* work evolved from a simpler one devised by Forrester, who had earlier devised structurally similar models of corporations and of cities. [e] Major subdivisions of the *Limits* model include capital investment, pollution, resources, population, and agriculture. In many instances, the feedback loops linking variables in these subdivisions incorporate time delays reflecting lags between environmental change and response, which are common in both biological and social systems. Thus, for example, capital investment in the health-service sector of the economy leads after a time lag to improved health care, which -- along with factors related to crowding, nutrition, and pollution -- influences life expectancies and hence population size.

When supplied with conditions at some starting point in time, the *Limits* computer model traces out the subsequent behavior of the major system variables -- population, resources, pollution, and some others -- based on the assumptions in the model. The resulting output takes the form of graphs displaying the rise and fall of the system variables as time goes by. As they appear in *Limits to Growth*, these graphs are dated only at rather wide intervals -- 1900, 2000, 2100. This is perfectly reasonable, since the results are intended simply to be indicative of the sorts of behavior the world system is prone to, rather than predictions of exactly what the state of the system will be on a specific date. It could hardly be otherwise, since considerations of computer capacity and running time (to say nothing of uncertainties concerning the way the world works) dictate that much detail be omitted.

Contrary to some of the criticisms of *Limits to Growth* that have been published, however, such simplification does not invalidate the results. Indeed, those who construct mathematical models of all kinds consciously *avoid* reproducing the system being studied in all its details; if they did not, the model would be as difficult to deal with as the real world. The essence of modeling is to include in the model only those variables and interconnections that are truly critical, thus

yielding the central features of the behavior of the system without an impenetrable array of details.

Of course, it is possible to err on the side of simplifying too much. The *Limits* model considered only one class of generalized pollutants and one class of generalized resources, each having properties thought to be representative of the most important items in the actual categories. There is also only one population, whose characteristics in the model represent in some sense an average of all the world's different populations. These are major approximations, and it may reasonably be asked whether what has been left out of the model, such as the interaction between different societies responding very differently to the same sorts of environmental change, is not just as important as what has been included. The authors of *Limits to Growth* recognized the need to investigate this question. They and others encouraged by them have devoted much effort to developing more detailed models and to testing the sensitivity ot the results to the various assumptions used. [f]

On the question of sensitivity to assumptions, many technologists have claimed that a different (and cheerier) result can be obtained from the *Limits* model by making modest changes in assumptions. The work that is generally quoted in support of this contention, however, deals not with the *Limits* model but with Forrester's earlier one, and it does not in fact support the contention at all. [g] The investigator was able to make the original Forrester model reach a utopian result only by assuming that a sixfold increase in technology over the 1970 levels would lead to an eightfold increase in food production, and that a fourfold increase in

technology would reduce resource input and pollutant output per unit of material standard of living to zero.

The first assumption is contrary to all recent experience; doublings of agricultural productivity have required triplings and quadruplings of technological inputs. The second assumption is impossible in principle since it violates the second law of thermodynamics, one of the most thoroughly verified laws of nature. All one could safely conclude from this work is that Forrester's model is "sensitive" to the introduction of miracles into the assumptions. Presumably, the more sophisticated model in *Limits to Growth* would also be "sensitive" in this way, but that is hardly a defect.

The most detailed critique of the *Limits* model was performed by a group at the University of Sussex, England, and was published together with a reply by the authors of *Limits of Growth* in a book called *Models of Doom*. [h] The Sussex critics accused the *Limits* group of leaving out economics and social change, of underestimating the power of technology, and of daring to make policy recommendations on the basis of a flawed model. The response of the Limits group was

that their model probably overestimated the effec tiveness of the price mechanism rather than underestimated it, that evidence of the limitations of technology has been accumulating rapidly, that in the absence of any perfect models one must make policy recommendations with the best ones available, and that social change (which is hard to model) is precisely what they were trying to stimulate by their recommendations. On the issue of whether the model overstated or understated the imminence of disaster, we might add that the simplistic treatment of environmental risks probably understated the danger more than other flaws overstated it.

Probably the most imposing attempt to construct a more realistic model than that in Limits was described in 1974 in Mankind at the Turning Point. The Second Report to the Club of Rome, by M. Mesarovic and E. Pestel. This model divided the world into ten political/geographical regions, modeling each of these on five "strata": (1) physical environment; (2) technology; (3) economic systems; (4) institutional and social responses; and (5) individual needs and responses.

Notwithstanding *Turning Point* 's occasional gratuitous disparagement of the oversimplification in *Limits to Growth* (difficult to understand in view of its obvious debt to the earlier work), the conclusions were strikingly similar: continuation of recent trends in population growth, industrialization, and environmental disruption will lead to disaster; deliberate and massive social and economic change will be necessary to avoid this outcome. The added sophistication of *Turning Point*'s regional disaggregation, showing the problems that can arise from such interactions as competition among regions for scarce resources, should be welcomed. At the same time, it seems fair to say that the net effect of this added degree of detail is to make the prognosis *more* pessimistic than that in *Limits*, not less so. Basically, regional disaster or negative interactions leading to wars seem more imminent than a uniform global disaster, which was the only kind the aggregated model in *Limits* could reveal. (This, of course, is another conclusion that many analysts have reached over the years without benefit of computer modeling).

Obviously, the model in *Turning Point* is still far from perfect. Certainly neither it nor other computer models can be used to predict the future in detail. Nevertheless, computer modelcate insights about the implications of present trends, and it has the great advantage of requiring that assumptions about relevant relationships be made explicit. Surely this is an improvement over the situation most likely to prevail when people think about the future of a complicated world -- the "models" in their heads are full of assumptions that are not only unstated but perhaps even unrecognized. In short, those critics who believe the world cannot be modeled should stop thinking about the future entirely, for implicitly all who do are modeling in their heads.

The purpose of caring at all where humanity is going, of course, whether one finds out with or without the aid of a computer, is not prediction for its own sake. It is, rather, that if we do not like the projected consequences of present trends and values, we can take conscious action to change course.

---

[h] H. Cole, C. Freeman, M. Jahoda, K. Pravitt, eds., *Models of doom*, Universe Books, New York, 1973.

It has been claimed that the technology factor should be tackled first because it is the easiest to deal with. As should be clear from the preceding analysis, this is a completely misleading idea. If that approach alone were carried out, it would serve only to deepen the human predicament; even the most dramatic improvements in technology would ultimately be canceled by rising population and consumption levels.

The momentum inherent in population growth commits *Homo sapiens* to many decades of further increase under even the most optimistic assumptions. And the momentum of economic growth makes it unlikely that growth in consumption per person in rich nations can quickly be halted, either -- particularly as long as economic growth is erroneously perceived as a substitute for eliminating the gross inequities in the distribution of wealth. Since it seems both inevitable and just that the poor nations will press for growth in *their* economies, the misappropriation of the world's resources by rich countries must soon be confronted along with the more general problem of poverty in LDCs. If humanity ignores population growth, overconsumption, and maldistribution of wealth now because these problems are tough and chooses instead to deal only with the relatively easy technological questions, the prospects twenty or thirty years hence will be gloomy indeed. The momentum of population and consumption trends will still be committing world society to even more growth, but most of the easy technological tricks to soften its environmental impact will by then have been exploited. Moreover, the prospects for eventual prosperity in the LDCs, already slim, will be hopeless if the rich countries are permitted to go on looting the world's high-grade resources for their own extravagant consumption for a few more decades.

It is also clear that attacking each of the other factors in isolation -- growth of population or material consumption -- would be an equally futile exercise. The most draconian control of population growth will be of no avail if technology and consumption are not controlled as well. Suppressing growth of material consumption without providing technological improvement or population control -- the most unlikely eventuality -- might retard environmental damage, but at the cost of impoverishing all of humanity.

Obviously, the time is long past for quibbling about which factor in the human predicament is "most important." They are *all* important. Failure to come to grips with all the factors -- *simultaneously, now* -- will surely sabotage the future for people now alive and for generations to come. The following chapters explore some of the avenues by which humanity might avoid some of the more serious pitfalls ahead, starting with the knotty issue of population control.

CHAPTER 13
Population Policies

Of all things people are the most precious.

-- Mao Tse Tung

Any set of programs that is to be successful in alleviating the set of problems described in the foregoing chapters must include measures to control the growth of the human population. The potential goals of such measures in order of possible achievement are:

Reduce the *rate* of growth of the population, although not necessarily to zero.
Stabilize the *size* of the population; that is, achieve a zero rate of growth.
Achieve a negative rate of growth in order to *reduce* the size of the population.

Presumably, most people would agree that the only humane means of achieving any of these goals on a global basis is by reducing the birth rate. The alternative is to permit the death rate to increase, which, of course, will inevitably occur by the agonizing "natural" processes already described if mankind does not rationally reduce its birth rate in time.

Even given a consensus that curbing population growth is necessary and that limiting births is the best approach, however, there is much less agreement as to how far and how fast population

limitation should proceed. Acceptance of the first goal listed above requires only that one recognize the obvious adverse consequences of rapid population growth -- for example, dilution of economic progress in less developed countries, and aggravation of environmental and social problems in both developed and less developed countries. Economists and demographers, many of whom will not accept

the third goal at all and ascribe no urgency to the second, generally do espouse the first one (at least for the LDCs).

Accepting the second goal simply means recognizing that Earth's capacity to support human beings is limited and that, even short of the limits, many problems are related to population size itself rather than only to its rate of growth. Accepting the idea that stabilizing the size of the population is urgently necessary requires recognizing that the limits are already being approached and that, although technological and cultural change may eventually push the limits back somewhat, the prudent course is to halt population growth until existing problems can be solved. Virtually all physical and natural scientists accept the ultimate inevitability of halting population growth, and most of them accept the urgency of this goal. Much of the first part of this book has been an exposition of why the "inevitable and urgent" position is reasonable.

The most controversial goal is the third one listed above -- reducing the size of the human population. Accepting this goal implies a belief that there is an optimum population size and that this optimum has already been exceeded (or will have been exceeded by the time population growth can be stopped). It also implies that each society has a right -- indeed a responsibility -- to regulate its population size in reference to the agreedupon optimum. In a world where the right (and the responsibility) of married couples to determine their own family size has become a widely accepted notion only in the past generation or two, the idea that nations have such a right or obligation is a truly radical one. Unfortunately, humanity cannot afford to wait another quarter century for the idea to gain complete acceptance.

Given the threat to the environment posed by today's population in combination with today's technology, and given the menace this situation represents to an already faltering ability to provide enough food for the people now alive, it is clear that the human population is already above the optimum size. (How *far* above the optimum is more difficult to determine; see Chapter 12). It is, of course, conceivable that technological and social change will push up the optimum in the time it takes to bring population growth to zero. More probably, however, the population size will have to be reduced eventually to *below today's* level if a decent life is to be assured for everyone.

Whether this view of long-term necessity is accepted or not, of course, the goal of any sensible population policy for the immediate future is the same -- to gain control over growth. This chapter describes the recent evolution of population policies, explores some potential (but still largely unexploited) means of achieving such control over population growth, and discusses the interacting effects of other policies (especially development policies) on population growth.

FAMILY PLANNING

An essential feature of any humane program to regulate the size of the human population must be provision of effective means for individuals to control the number and timing of births. This approach is commonly termed "family planning," and family planning programs have been introduced in many LDCs in the past two decades with the goal of providing the means of birth control to the people. These are the main population policies now in existence.

The family planning movement, however, historically has been oriented to the needs of individuals and families, not of societies. Although birth control is essential for achieving population control, *family planning and population control are not synonymous*. Before proceeding to an examination of the important difference between the two, some historical perspective on the practice of birth control and the family planning movement is in order.

Birth Control

Many birth control practices are at least as old as recorded history. The Old Testament contains obvious references to the practice of withdrawal, or *coitus interruptus* (removal of the penis from the woman's vagina before ejaculation). The ancient Egyptians used crude barriers to the cervix made from leaves or cloth, and even blocked the cervical canal with cotton fibers. The ancient Greeks practiced population control through their social system as well as through contraception; they discouraged marriage and encouraged homosexual rela-

BOX 13-1 Institutionalized Infanticide in the Eighteenth Century*

Where the Number of lusty Batchelors is large, many are the merry-begotten Babes: On these Occasions, if the Father is an honest Fellow and a true Church of England-Man, the new-born Infant is baptized by an indigent Priest, and the Father provides for the Child: But the Dissenters, Papists, Jews, and other Sects send their Bastards to the Foundling Hospital; if they are not admitted, there are Men and Women, that for a certain Sum of Money will take them, and the Fathers never hear what becomes of their Children afterwards . . . in and about London a prodigious Number of Infants are cruelly murdered unchristened, by those Infernals, called Nurses; these detestable Monsters throw a Spoonful of Gin, Spirits of Wine, or HungaryWater down a Child's Throat, which instantly strangles the Babe; when the Searchers come to inspect the Body, and enquire what Distemper caused the Death, it is answered, Convulsions, this

occasions the Article of Convulsions in the Bills of Mortality so much to exceed all others. The price of destroying and interring a Child is but Two Guineas; and these are the Causes that near a Third die under the Age of Two Years, and not unlikely under two Months. I have been informed by a Man now living, that the Officers of one Parish in Westminster, received Money for more than Five Hundred Bastards, and reared but One out of the whole Number. How surprizing and shocking must this dismal Relation appear, to all that are not hardened in Sin? Will it not strike every one, but the Causers and Perpetrators with Dread and Horror? Let it be considered what a heinous and detestable Crime Child-murder is, in the Sight of the Almighty, and how much it ought to be abhorred and prevented by all good people.

tionships, especially for men. The condom, or penis sheath, dates back at least to the Middle Ages. Douching, the practice of flushing out the vagina with water or a solution immediately after intercourse, has had a similarly long history. Abortion is a very ancient practice and is believed to have been the single most common form of birth control in the world throughout history, even during the past century when it was illegal in most countries. The simplest, most effective, and perhaps the oldest method of birth control is abstention; but this method seems to have been favored mainly by older men, particularly unmarried members of the clergy.

Infanticide, which is viewed with horror today by prosperous people in industrialized societies, has probably always been practiced by societies lacking effective contraceptive methods. [1] It was a rather common practice among the ancient Greeks, and the Chinese and Japanese are known to have used it for centuries, especially in times of famine. In agrarian or warlike societies, female infanticide has often been practiced to provide a greater proportion of men or to consolidate upper classes. Only a century or two ago, infanticide was widely practiced in Europe in an institutionalized, although socially disapproved system sometimes called "baby farming" (Box 13-1). [2]

Infanticide rarely takes the form of outright murder. Usually it consists of deliberate neglect or exposure to the elements. Among the Eskimos and other primitive peoples who live in harsh environments where food is often scarce, infanticide was, until recently, a common practice, as greater importance was placed on the survival of the group than on the survival of an additional child. There is a strong suspicion that female infanticide persists in parts of rural India. It exists even in our own society, especially among the overburdened poor, although intent might be hard to prove. Certainly "masked infanticide" is extremely common among the poor and hungry in less developed countries, where women often neglect ill children, refuse to take them to medical facilities, and may even show resentment toward anyone who attempts treatment. According to Dr. Sumner Kalman of the Stanford University Medical Center, the average poor mother in Colombia -- where 80 percent or more of a large family's income may be needed to provide

food alone -- goes through a progression of attempts to limit the number of her children. She starts with ineffective native forms of contraception and moves on to quack abortion, infanticide, frigidity, and all too often to suicide. [3]

The development of modern methods of contraception and the spread of family planning have eliminated the need for such desperate measures as infanticide and self-induced abortion in most developed nations and among the wealthier classes of most less developed countries. But modern methods of birth control are still by no means available to every potential parent in the world. The most effective contraceptives -- oral contraceptives (Figure 13-1), IUDS, and safe, simple sterilization -- have been available even to the affluent only since the early 1960s. A description of the modern methods of birth control most used today and others still under development can be found in Appendix 4 in the back of this book.

Family Planning: A Short History

During the Industrial Revolution in England, an early advocate of limiting the size of families through contraception was labor leader Francis Place. Realizing that a limited labor pool would be likelier to win high wages and better working conditions from employers than would a plentiful supply of workers, in 1822, Place published a treatise, *Illustrations and Proofs of the Principle of Population*, which reached large numbers of people. [4] This was followed by a series of handbills that urged birth control in the interest of better economic and physical health and also described various contraceptive methods. Additional books on birth control appeared both in England and the United States during the 1830s and continued to circulate until the 1870s, when legal attempts were made to suppress them in both countries. The attempt failed in England, but in the United States the "Comstock Law" was passed by Congress in 1873. It forbade the dissemination by mail of birth control information, classing it as "obscene literature." Many states also passed laws against birth control literature, known as "little Comstock laws," and in 1890 importation of such literature was outlawed. [5]

America's heroine in the family planning movement was Margaret Sanger, a nurse. Her main objective was to free women from the bondage of unlimited childbearing through birth control, and her efforts thus were a part of the women's emancipation movement. In 1916 Mrs. Sanger opened the first birth control clinic in Brooklyn, for which she was arrested and jailed. As a result of her case, however, court decisions subsequently permitted physicians to prescribe birth control in New York for health reasons.

These were the first of many such decisions and changes in state laws that ultimately permitted the sale and advertisement of contraceptive materials and the dissemination of information about birth control. But the change was slow. The last such court decision was made in 1965, when the U.S. Supreme Court ruled that the Connecticut statute forbidding the use of contraceptives was an unconstitutional invasion of privacy. In 1966 the

[5] W. Best and L. Dupré, *Birth control*. Much of the historical material in this section is based on this source.

Massachusetts legislature repealed the last of the state Comstock Laws. Margaret Sanger and others who joined her rapidly growing birth control movement (first known as the Birth Control League, later as the Planned Parenthood Federation) after World War I led the fight for these legal changes and for support from medical, educational, health, and religious organizations.

Counterparts to Margaret Sanger existed in many other countries, especially in northern and western Europe, and planned parenthood movements became independently established in several nations. Their founders, like Mrs. Sanger, were motivated primarily by concern for the

health and welfare of mothers and children, and their campaigns emphasized these considerations.

Concurrently, intellectual organizations concerned primarily with population growth, known as Malthusian Leagues, were also promoting birth control. These, of course, were intellectual descendants of Robert Malthus, who first put forth warnings about the dangers of overpopulation (see Box 13-2). They were active in several European countries; but after World War I, when European birth rates had reached quite low levels, Malthusian concerns seemed to lose relevance and the movement died out.

The birth control movement in the United States was at first opposed by the medical profession. As the health and welfare benefits of family planning became apparent, the medical profession moved to a position of neutrality. In 1937 the American Medical Association (AMA) finally called for instruction on contraception in medical schools and medical supervision in family planning clinics. But it was not until 1964 that the AMA recognized matters of reproduction, "including the need for population control," as subjects for responsible medical concern. [6]

Religious opposition to the birth control movement was initially even stronger than medical opposition. The Roman Catholic church still opposes "artificial" methods of birth control, but Planned Parenthood clinics cooperate in teaching the rhythm method to Catholics who request it. Acceptance of birth control came gradually from the various Protestant and Jewish groups after initial opposition. Official sanction was given by the Anglican (Episcopal) Communion in England and the United States in 1958, by the Central Conference of American Rabbis (Reform) in 1960, and by the National Council of Churches in 1961.

Birth rates in America and Europe had already begun to decline long before the first birth-control clinics were established (Chapter 5). Nevertheless, the familyplanning movement, particularly in the United States, probably deserves some credit for today's relatively low birth rates. It certainly played a great role in increasing the availability of contraceptives and birth control information. This was accomplished not so much through Planned Parenthood clinics, which never have reached more than a small fraction of the total population, but through the removal of restrictive laws, the development of medical and religious support, and the creation of a social climate in which birth control information could circulate freely. Since passage of the *U.S. Family Planning Act in 1970*, Planned Parenthood clinics have been a major provider of free and low-cost contraceptive services to low-income people through government grants.

Throughout its history, the emphasis and primary concern of the family planning movement has been the welfare of the family; it has stressed the economic, educational, and health advantages of well-spaced, limited numbers of children. [7] Its policy has been to provide information and materials for birth control in volunteerstaffed clinics, serving any interested client, but primarily the poor who could not afford treatment by a private physician. Once the movement was established in the United States, little effort was made to recruit clients, beyond the routine promotion that accompanied the opening of a new clinic. For the United States this policy was apparently adequate; this nation is now overwhelmingly committed to the idea of family planning and the practice of birth control.

Contraceptive practice in the United States. By 1965, survey results showed that some 85 percent of married women in the United States had used some method of birth control. Most by then favored the more effective methods such as the pill. Among older couples,

[6]Best and Dupré, *Birth control*.

[7]These advantages are very real, as the World Health Organization has recently confirmed. See Dr. Abdel R. Omran, *Health benefits for mother and child*.

BOX 13-2 Thomas Robert Malthus, 1766-1834

The name Malthus and the terms Malthusian and neo-Malthusian are so completely identified with concern about population pressure that a note about the man seems appropriate. Robert Malthus enjoyed what was certainly one of the happiest personal situations ever devised by man; he was an eighteenth-century English country gentleman of independent means. His youth and early manhood were spent in the last years of the Enlightenment, the Age of Reason, a time when learned and wise men saw themselves on the threshold of a world of concord among men and nations in which want and oppression would not exist. Man's imminent entry into this paradise was to be achieved through his discovery of the immutable Laws of Nature which were thought to be such that they could be understood by the human faculty of Reason. All discord, want, and cruelty, were held to result from an ignorance of these Laws, which led man to their disobedience. It was an age of very great hope when Nature and Reason were enshrined.

Malthus' father, Daniel, the very embodiment of these values, was well connected in the intellectual and philosophical circles of the time, being a close associate of David Hume and a correspondent, friend, and finally, an executor of Jean Jacques Rousseau.

In 1784, after a preparation through home tutoring, Malthus entered Cambridge, where in 1788 he graduated with first-class honors in mathematics. With graduation he took Holy Orders in the Church of England but remained at Cambridge, where he achieved his M.A. in 1791 and became a Fellow of his College in 1793. In 1796 he became curate of the church at Albury, where his father resided, and settled down to country life.

These were the years of the French Revolution, years that Dickens called "the best of times, the worst of times." Neither the Revolution's war, internal and external, nor even its Terror yet

dampened the ambience of optimism that characterized the world of thought. In 1793 William Godwin published his *Enquiry Concerning Political Justice* and the next year saw the appearance of the Marquis de Condorcet's *Essay on the Progress of the Human Spirit*, both of which sought to demonstrate that man's progress from darkness, superstition, and cruelty into the light of Concord through Reason was almost complete. Daniel Malthus, like most of the thoughtful men of the time, was much taken by these writings, but Robert could not share his enthusiasm. Cambridge had not, as he put it, given him "that command over his understanding which would enable him to believe what he wished without evidence." The concern that haunted Robert was population growth. How could a perfect society be achieved, let alone maintained, if population was constantly pressing against resources? Finally, Robert committed his misgivings to writing so he could present them systematically to his father. Daniel was so impressed with the arguments that he encouraged his son to publish them, which he did anonymously in 1798, under the title, *An Essay on the Principle of Population as it Affects the Future Improvement of Society With Remarks on the Speculations of Mr. Godwin, M. Condorcet and Other Writers*. His speculations centered on the proposition that man's "power of population is indefinitely greater than the power in the earth to produce subsistence. . . ." This he propounded with strict immutability and mathematical regularity characteristic of the Natural

sterilization had become the single most popular method. By 1970 one-quarter of American women over 30 either were sterilized or their husbands were; by 1973, 23 percent of married couples of all ages relied on sterilization for birth control. Most of the women not using birth control in the 1965 and 1970 surveys were subfertile, pregnant, or planning to use contraceptives only when their families were complete. Moreover, despite the official position of the Roman Catholic church, Catholic women in these surveys showed a level of use of "artificial" contraceptives nearly as high as that of non-Catholic women. [8]

How much of recent U.S. population growth was due to unwanted births has been a matter for debate among demographers. The National Fertility Study of 1965 indicated that 17 percent of all births between 1960 and

[8] Charles F. Westoff, Changes in contraceptive practices among married couples, in Westoff, ed. *Toward the end of growth, population in America*; C. F. Westoff and L. Bumpass, *The revolution in birth control practices of U.S. Roman Catholics*.

Laws of the Age of Reason as "population, when unchecked, increases in a geometrical ratio. Subsistence increases only in an arithmetical ratio . . ." The first *Essay* challenged the visions of an age and the reactions were immediate and predictably hostile, though many listened. The controversy led to the publication in 1803 of an enlarged, less speculative, more documented, but equally dampening second essay. This one was signed and bore the title, *An Essay on the Principle of Population or a View of its Past and Present Effects on Human Happiness with an Inquiry into our Prospects Respecting the Future Removal or Mitigation of the Evils it*

Occasions. [*] Malthus added to and modified the *Essay* in subsequent editions, but it stood substantially unchanged.

In 1804 he accepted a post at the East India Company's college at Haileybury which prepared young men for the rule of India, where he remained until his death. His marriage, in the same year, ultimately produced three children.

The ironies in Malthus' life are obvious. He was one of eight children. He occupied a position of comfort in an intellectual atmosphere of optimism, but was compelled by the rigor of his intellect to argue that nature condemned the bulk of humanity to live in the margin between barely enough and too little. Finally, his message as a teacher fell on the ears of future colonial bureaucrats who would guide or preside over the destinies of India.

Since the conversations between Robert Malthus and his father almost two centuries ago, two sets of factors which were beyond their ken have emerged. The first set combined to put elements into a population-subsistence relationship that Malthus could not have foreseen. On one hand, the introduction of massive death control procedures -- immunization, purification of drinking water, the control of disease-carrying organisms, improved sanitation, etc.--have removed many of the checks that Malthus assumed as "natural." On the other hand, developments in agriculture -- high-yield plant strains, the powering of equipment with fossil fuels, the use of new techniques of fertilization and pest control -- have massively increased food production.

The second set of factors has become widely significant only in the last quarter century and evident to most laymen only in the last decade. These are the deleterious effects on the biosphere resulting from agriculture and industry. With our planet's population bloated by death control and sustained only poorly through an agriculture based on nonrenewable resources and techniques which buy short-run, high yields at the expense of long-run, permanent damage to the "Earth's power to produce subsistence," we face a prospect inconceivable in the Age of Reason. Malthus looked into a dismal future of "vice and misery" begot of an uncontrolled, and, to his mind, uncontrollable population growth. We look into one where the dismal is compounded with peril, not because humanity cannot control its population, but because it *will* not. [**]

1965 were not wanted by both parents and 22 percent were not wanted by at least one parent. The incidence of unwanted births was found, not unexpectedly, to be highest among the poor, to whom birth control and safe abortion were least available. Demographer Charles Westoff estimated that eliminating such a high proportion of unwanted births might reduce the U.S. rate of natural increase by as much as 35 to 45 percent. [9]

However, another distinguished demographer, Judith Blake, pointed out that the high incidence of unwanted births calculated by Westoff for the U.S. during 19601965 was caused in large part by births occurring disproportionately to women who already had several children. [10] During those six years, there were unusually small proportions of first and second children born and unusually large proportions of births of higher orders (which are more likely to be unwanted). Hence, due to

Bonar , *Malthus and his work*, 2d ed., 1924; G. F. McCleary, *The Malthusian population theory*; and, of course, Malthus' First and Second Essays.

[10] Reproductive motivation and population policy.

[9] L. A. Westoff and C. F. Westoff, *From now to zero: fertility, contraception and abortion in America*.

the age composition of the population, the *total* proportion of unwanted births in the U.S. was higher for those years than it has been at other times.During the late 1960s, such changes as the increasing use of the pill and IUDs and relaxation of restrictions against voluntary sterilization substantially reduced the incidence of unwanted births of all orders. Results of the 1970 National Fertility Study confirmed this change, indicating that only about 14 percent of births between 1965 and 1970 were unwanted. [11] Most of the reduction in fertility in that period was due to reductions in unwanted and unplanned births. Since 1970, the extension of family planning services to the poor and the reversal of abortion laws (see below) have evidently further extended the trend, as attested by record low fertility rates.There is no question that providing better contraceptives and simplified sterilization procedures, legalizing abortion, and ensuring that all are easily available to all members of the population reduces the incidence of unwanted pregnancy -- a socially desirable end in itself. But even if a perfect contraceptive were available, the contraceptive-using population probably never will be perfect. People forget, are careless, and take chances. They are also often willing to live with their mistakes when the mistakes are babies. The complete elimination of unwanted births therefore is probably not possible. Nor does that alone account for the dramatic drop in the U.S. birth rate in the early 1970s. Rather, it appears that a significant change in family-size goals took place around that time, especially among young people who were just starting their families. [12] Changing attitudes in the United States. Public surveys taken between 1965 and 1972 revealed a growing awareness of the population problem on the part of the American public. In 1965, about half of the people interviewed in a Gallup Poll thought that U.S. population growth might be a serious problem; in 1971, 87 percent thought that it was a problem now or would be by the year 2000. In January 1971 only 23 percent of adults polled thought four or more children constituted the ideal family size, in contrast to 40 percent in 1967. One of the three most commonly given reasons for favoring small families in 1971 was concern about crowding and overpopulation; the others were the cost of living and uncertainty about the future.In October 1971, a survey sponsored by the U.S. Commission on Population Growth and the American Future disclosed a still greater level of concern about the population explosion among Americans. Specifically, it was discovered that:

Over 90 percent of Americans viewed U.S. population growth as a problem; 65 percent saw it as a serious problem.

Over 50 percent favored government efforts to slow population growth and promote population redistribution.

Well over 50 percent favored family limitation even if a family could afford more children.
About 56 percent favored adoption after births of two biological children if more were desired.
Only 19 percent felt that four or more children were the ideal number for a family; 45 percent favored two or less. The mean was 2.33.
Only 8 percent thought the U.S. population should be larger than its current size.

Concurrent with the rise in public concern about population growth, Zero Population Growth, Inc., was founded in late 1968 to promote an end to U.S. population growth through lowered birth rates as soon as possible and, secondarily, to encourage the same goal for world population. The organization hoped to achieve this by educating the public to the dangers of uncontrolled population growth and its relation to resource depletion, environmental deterioration, and various social problems; and by lobbying and taking other political action to encourage the development of antinatalist policies in the government. Since its founding, ZPG has taken an active role in promoting access to birth control for all citizens, legalized abortion, women's rights, and environmental protection. More recently it has begun to explore changes in U.S. immigration policies. ZPG has clearly been a factor in changing attitudes toward family size and population control.

[11]Charles F. Westoff, *The modernization of U.S. contraceptive practice*; Trends in contraceptive practice: 1965-1973; The decline of unplanned births in the United States.

[12]U.S. Bureau of the Census, *Fertility history and prospects of American women: June 1975*.

The growth of the women's liberation movement in the U.S. since 1965 has almost certainly been another important influence on attitudes (and thus on birthrates) through its emphasis on opportunities for women to fulfill themselves in roles other than motherhood. Many young women today are refreshingly honest about their personal lack of interest in having children and their concern for obtaining opportunities and pay equal to those of men. Such attitudes were virtually unthinkable in the United States before 1965.

The women's movement was a potent force behind the liberalization of U.S. abortion laws, and has also actively campaigned for the establishment of low cost day-care centers for children and tax deductions for the costs of child care and household work. Such facilities and policies lighten the costs of childbearing, but they also encourage mothers to find work outside the home. The experience of many societies suggests that outside employment of mothers discourages large families more than the existence of child-care facilities encourages them.

Both the growing concern about the population problem and the ideas of women's liberation doubtless contributed to changing attitudes toward family size in the 1970s. The economic uncertainty of the period may also have been a factor. While it may never be possible to determine the causes exactly, the achievement of subreplacement fertility in the United States is one of the most encouraging developments since 1970.

POPULATION POLICIES IN DEVELOPED COUNTRIES

Although birth control in some form is almost universally practiced in developed countries, very few have formulated any explicit national policies on population growth other than regulation of migration. Some European countries still have officially pronatalist policies left over from before World War II, when low birth rates led to concern about population decline.

Of course, many laws and regulations enacted for economic, health, or welfare reasons have demographic effects: for instance, those governing the availability of contraceptives, sterilization, and abortion; marriage and divorce; income taxes and family allowances; and immigration regulations.

The United States

The United States has no specific population policy, although various laws, including those regulating immigration and the administration of income taxes, have always had demographic consequences. Most tax and other laws were until recently implicitly pronatalist in effect. In the late 1960s this situation began to change as state laws restricting the distribution of contraceptive materials and information were repealed and as abortion laws were relaxed in several states. In 1970 Congress passed the *Family Planning Services and Population Research Act*, established the Commission on Population Growth and the American Future, and passed the *Housing and Urban Development Act*, which authorized urban redevelopment and the building of new towns. In 1972, an amendment to the Constitution affirming equal rights for women passed Congress, but as of 1977 it was not yet ratified by the required number of states.

The *Family Planning Services and Population Research Act of 1970* had the goal of extending family planning counselling and services to all who needed them, particularly the poor. It also provided funds for research on human reproduction. Some 3.8 million women were being provided with family planning services by 1975, 90 percent of whom had low or marginal incomes. Another 1.9 million were being served by private physicians. But it has been estimated that another 3.6 million eligible women (including about 2.5 million sexually active teenagers) were still not receiving needed help in the mid-1970s. Particularly neglected were women in rural areas and small towns. Governmentsubsidized services have been provided through local health departments, hospitals, and private agencies (primarily Planned Parenthood), most of which are located in urban areas. A leveling-off of increases in clients in 1974 and 1975 over previous years has been attributed mainly to lack of increased funding by the government rather than to lack of need. [13]

[13] Marsha Corey, *U.S. organized family planning programs in F 1974*; Joy G. Dryfoos, *The United States national family planning program, 1968-74*; The Alan Guttmacher Institute, *Organized family planning services in the United States: FY 1975*; T. H. Firpo and D. A. Lewis, *Family planning needs and services in nonmetropolitan areas*.

Since 1967, the U.S. Agency for International Development (AID) has been permitted to include family planning assistance in its programs. Funding for overseas family planning assistance has been steadily increasing since then, and by fiscal 1976 had reached a level of $201.5 million. [14]

The U.S. Commission on Population Growth and the American Future presented its findings and recommendations in 1972 in the areas of demographic development, resource utilization, and the probable effects of population growth on governmental activities. [15] After two years of study, the Commission concluded that there were no substantial benefits to be gained from continued population growth, and indeed that there were many serious disadvantages. Besides recommending the liberalization of abortion laws and numerous other population-related policies, the report strongly recommended that contraceptives be made available to all who needed them, including minors; that hospital restrictions on voluntary sterilization be relaxed; that sex education be universally available; and that health services related to fertility be covered by health insurance. It also recommended policies to deal with immigration, population distribution, and land use. Perhaps most important, the Commission stated:

Recognizing that our population cannot grow indefinitely, and appreciating the advantages of moving now toward the stabilization of population, the Commission recommends that the nation welcome and plan for a stabilized population. [16]

Unfortunately, apart from expressing strong disagreement with the recommendations on abortion, President Nixon took no action on the Commission's report, nor did President Ford show any inclination to do so. The abortion question was made moot by the Supreme Court's decision in 1973 (see section on abortion below). Congress has contented itself mainly with expanding federal family planning services. Thus, although the United States has not hesitated to advocate the establishment of official antinatalist population policies in less developed countries, it has not established one for itself.

The current low fertility of American women seems to have taken the urgency from the zero population growth movement -- even though that fertility trend could easily reverse itself at any time. Given its present age composition, the U.S. still could reach the higher population projections of the Census Bureau (Chapter 5) if another baby boom occurred. In the mid-1970s, however, no consensus for immediate ZPG existed, and interest in population problems has been focused on aspects other than the birth rate -- primarily on distribution and immigration.

Social objections to ZPG. The proposal to stop population growth naturally aroused considerable opposition on religious, social, and economic grounds. The role of religion in determining attitudes toward population growth, as well as toward the environment and resource limitation, is discussed in more detail in Chapter 14.

The primary social argument that has been raised against halting U.S. population growth is that it would substantially change the nation's age composition. [17] As the population stabilized, the median age would increase from about 28 to about 37. Less than 20 percent of the population would then be under 15, and about the same percentage would be over 65 years old. At present, about 25 percent of the population is under 15, and 11 percent is over 65. It is assumed that such an old population would present serious social problems. Figure 5-15 (Chapter 5) shows the age compositions of the U.S. in 1900 and 1970 and how it would look in a future stationary population.

It is true that old people tend to be more conservative than young people, and they seem to have difficulty adjusting to a fast-changing, complex world. In an older population there would be relatively less opportunity for advancement in authority (there would be nearly as many 60 year-olds as 30 year-olds -- so the number of potential

[15]*Population and the American future*.

[16]*Population and the American future*. By a "stabilized population," the Commission meant a stationary one.

[17]Ansley J. Coale, "Man and his environment", *Science*, vol. 170, pp. 132-136 (9 Oct 1970).

chiefs would be about the same as the number of Indians). There would also be many more retired people, a group already considered a burden on society.

But even those who raise this argument must realize its fundamental fallacy. In the relatively near future, growth of the human population will stop. It would be far better for it to stop gradually through birth limitation than by the premature deaths of billions of people. (In the latter case, there would be other, much more serious problems to worry about). Therefore, if this generation does not initiate population control, we simply will be postponing the age composition problems, leaving them to be dealt with by our grandchildren or great grandchildren. Our descendants will be forced to wrestle with these problems in a world even more overcrowded, resource-poor, and environmentally degraded than today's.

Moreover, the assumption that an older population must be much less desirable than a younger one is questionable in this society. Today, chronic underemployment and high unemployment are exacerbated by a labor pool constantly replenished by growing numbers of young people, which forces early retirement of the old, making them dependents on society. Many of our current social problems, including the recently skyrocketing crime rates and serious drug problems, are associated with the younger members of the population. If population growth stopped, the pressure of young people entering the labor pool would decline, while crime and unemployment problems could be expected to abate, as would the need for forced retirement of older workers.

Old people today are obsolete to a distressing degree. But this is the fault of our social structure and especially of our educational system. The problem with old people is not that there are or will be so many of them, but that they have been so neglected. If underemployment were reduced, outside interests encouraged during the middle years, and education continued throughout adult life (as suggested in Chapter 14), older people would be able to continue making valuable contributions to society well into their advanced years. Maintaining the habits of active interest in society and learning new, useful skills might effectively prevent obsolescence and the tendency to become conservative and inflexible with advancing age.

Thus, although there may be some disadvantages to an older population, there are also some definite advantages. While the proportion of dependent retired people grew, that of young children would shrink. The ever-rising taxes demanded in recent decades to support expanding school systems and higher educational facilities would cease to be such a burden; indeed, that has begun to happen already. The same is true of resources now devoted to crime control and other problems primarily of young people. Some of that money could be diverted instead to programs to help the aged. Moreover, the growth in the proportion of senior citizens (the numbers will not change; they are already born) will be far more gradual than the decline in numbers of babies and small children that has already occurred, allowing ample time for society to adjust to the change.

In the meantime, if birth rates remain low, the overall dependency ratio of the population will decline. In 1970 there were 138 dependents for every 100 workers in the United States; by 1980 the ratio will drop to about 118 and may be 112 or less by 1990. [18] Even after the numbers of the aged begin to rise in the population, the dependency ratio will remain relatively low. As Kingsley Davis pointed out, the highest proportion (about 75 percent) of people in productive ages (15-65) is found in a population that is making the transition from growth to ZPG. The proportion is nearly as high in a stationary population (about 63 percent). [19] And if years of productivity were extended to 70 and beyond, the proportion would be even higher, of course. By contrast, in very rapidly growing LDC populations, the proportion of people in their productive years (15 to 65) can be 50 percent or less.

Economic objections to ZPG. The economic objections to ZPG are based upon the realization that a nongrowing population implies at least a much more slowly growing economy, if not a nongrowing one. This thought strikes fear in the breasts of most businessmen and economists, even though a perpetually growing economy is no more sustainable than a perpetually growing population. The implications of a steady-state economy are discussed in Chapter 14; here we limit

[18] U.S. Bureau of the Census, *Population of the United States: Trends and prospects 1950-1990*.
[19] *Zero population growth: the goal and the means*. no. 4, 1973, pp. 15-30.

ourselves to some of the aspects more obviously related to population growth. [20]

In 1971, economist J. J. Spengler noted the economic advantages and disadvantages of ZPG. [21] One of the advantages is increased productivity per person, partly because of greater capital available for investment, and partly because of a reduced dependency ratio. Other advantages include stabilized demand for goods and services; increased family stability as a result of there being fewer unwanted children; reduction of costs of environmental side effects; and opportunities to minimize the effects of population maldistribution. On the minus side, Spengler mentioned the problems associated with the changed age structure and pointed out that there would be a relative lack of mobility for workers and less flexibility in the economy because there would be fewer entrants into the labor force. He was also concerned that there might be a tendency toward inflation, due in part to increases in the service sector and in part to pressure to

raise wages more than rising productivity justified. Recent events, as population growth has slowed (though there is not yet a decline in growth of the labor pool), suggest that Spengler may be right about the inflation pressures, although many other influences clearly are involved too. And certainly there are ways to compensate for those pressures.

The question of labor shortage for an expanding economy in a stationary population has also been raised. But, as economist Alan Sweezy has pointed out, workers (and their families) are the main consumers as well as the producers. [22] And, as mentioned above, the productive portion of a population is largest in stationary and transitional populations.

There was speculation by economists during the 1930s and 1940s that consumption patterns would be drastically, and presumably adversely, changed if population growth stopped. But a recent study comparing consumption patterns in the U.S. population of 1960/ 1961 (when it was growing relatively fast) with those of a projected stationary population indicated that the changes would be surprisingly minor. [23] The most notable difference was that there would be proportionally more households (called *spending units* by economists) in an older stationary population; families would be smaller but more numerous. Many of the changes in actual spending patterns would balance each other; in a stationary population there would be a greater demand for housing, for instance, but a lower demand for clothing and transportation. In no case were the changes more than a few percent.

Differential reproduction and genetic quality. A common concern about population control is that it will in some way lead to a reduction in the genetic quality of *Homo sapiens*. [24] This concern is often expressed in such questions as "if the smart and responsible people limit their families while the stupid and irresponsible do not, couldn't that lead to a decline of intelligence and responsibility in humanity as a whole?" The technically correct answer is "no one knows"; the practical answer is "there is no point in worrying."

No one knows, because it is not at all clear what, if any, portion of the variation in traits like "intelligence" or "responsibility" (however defined, and definition is difficult and controversial) is influenced by genetics. The most intensively studied example of such "mental" traits is performance on various so-called intelligence tests, and it has not been possible to demonstrate unambiguously that genes make any significant contribution to an individual's scores. [25]

There is no point in worrying about it because, even if these traits had a substantial genetic component and people with "bad" genes greatly outproduced people with "good" ones, it would take a great many generations (hundreds of years at a minimum) for the differential reproduction to produce a socially significant effect. Moreover, if such an effect were discovered, it could then

[24]For discussion of this question, see papers in C. J. Bajema (ed), *Natural selection in human populations*.
[25]See especially Leon J. Kamin, *The science and politics of IQ for a critique of the twin data on which most of the evidence for the heritability of IQ rests*.

be reversed either by reversing the selective pressures (for example, encouraging reproduction of those with high IQ test scores) or, more likely, by modifying the social environment in order to improve the performance of those with poor scores ("bad" genes).

Note that we have put quotation marks around "good" and "bad." It is common for nonbiologists to think that heredity is a fixed endowment that rigidly establishes or limits skills, abilities, attitudes, or even social class. In fact, heredity is at most one of two sets of interacting factors, the other being the cultural and physical environment. When heredity does play a significant role (and it often may not), it is the *product* of this interaction that is of interest, and that product may be modified very effectively by changing the environment. [26] There is therefore no need for deep concern about the possible genetic effects of population control.

Another related issue that seems to encourage a pronatalist attitude in many people is the question of the *differential reproduction* of social or ethnic groups. Many people seem to be possessed by fear that their group may be outbred by other groups. White Americans and South Africans are worried there will be too many blacks, and vice versa. The Jews in Israel are disturbed by the high birth rates of Israeli Arabs, Protestants are worried about Catholics, and Ibos about Hausas. Obviously, if everyone tries to outbreed everyone else, the result will be catastrophe for all. This is another case of the "tragedy of the commons," wherein the "commons" is the planet Earth. [26a] Fortunately, it appears that, at least in the DCs, virtually all groups are exercising reproductive restraint.

For example, in the United States fertility in the black population has consistently been higher than white fertility (black mortality has also been higher). Since birth control materials and information began to be made available to low-income people in the late 1960s, black fertility has been declining even more rapidly than white fertility. By 1974, black women under 25 expected to have essentially the same number of children as white women their age: an average of 2.2 (see Box 13-3). [27]

The ideal situation, in our opinion, would be for all peoples to place a high value on diversity. The advantages of cultural diversity are discussed in Chapter 15; the reasons for avoiding a genetic monoculture in *Homo sapiens* are essentially the same as those for avoiding one in a crop plant--to maintain resistance to disease and a genetic reservoir for potential adaptation to changed environments in the future. The advantages also include the possibility of aesthetic enjoyment of physical diversity. [28] Some day we hope that whites will become distressed if blacks have too few children, and that, in general, humanity will strive to maximize its diversity while also maximizing the harmony in which diverse groups coexist.

Distribution and mobility. Obscuring the population controversy in the United States in the late 1960s was the tendency of some demographers and government officials to blame population-related problems on population maldistribution. The claim was that pollution and urban social problems are the result of an uneven distribution of people, that troubled cities may be overpopulated, while in other area of the country the population has declined. [29] The cure promulgated in the 1960s was the creation of "new cities" to absorb the 80 million or so people then expected to be added to the U.S. population between 1970 and 2000.

It is of course true that there is a distribution problem in the United States. Some parts of the country are economically depressed and have been losing population--often the most talented, productive, and capable elements--while other areas have been growing so rapidly that they are nearly overwhelmed. Patterns of migration and settlement are such that residential areas have become racially and economically segregated to an

---

[26] A detailed explanation for the layman of the complex issues of the inheritance of intelligence can be found in P. Ehrlich and S. Feldman, *Race bomb*. See also F. Osborn and C. J. Bajema, *The eugenic hypothesis, for an optimistic evaluation of the genetic consequences of population control*.

[26a] Garrett Hardin, *The tragedy of the commons*.

[27] Frederick S. Jaffe, *Low-income families: fertility changes in the 1960s*; Population Reference Bureau, *Family size and the black American*.

[28] There is more genetic variation *within* groups of human beings than between them, but some of the inter-group variation may be biologically important (and is more widely recognized by lay persons).

[29] For instance, demographer Conrad Taeuber, who supervised the 1970 U.S. Census, in a speech delivered at Mount Holyoke College in January 1971 (quoted in the *New York Times*, Jan 14, 1971).

BOX 13-3 Poverty, Race, and Birth Control in the United States*

The entrance of the United States government into the field of birth control through the extension of family planning services to the poor aroused a controversy quite out of proportion to its potential effect on the national birth rate, particularly in the black community, some members of which perceived it as a policy of "genocide" against racial minorities.

In the United States, birth rates have long been higher among the poor and among nonwhites (blacks, orientals, and native Americans) than among the nonpoor and among whites. High birth rates are generally associated with low economic and educational levels in most countries, including the United States. At the same time, the poor and nonwhites also have had consistently higher death rates, especially among infants and children. Above the poverty level, the birth rate difference between races diminishes, and college-educated nonwhites have *fewer* children than their white peers. In recent years (especially since the national family planning program was established) the birth rates of the poor and nonwhites have been declining even more rapidly than those of the population as a whole. **

Although there is conflicting evidence regarding desired family size among the poor, several surveys conducted in the 1960s indicated that poor couples wished to have only slightly more children than middle-class couples, and nonwhite couples in most socioeconomic classes wanted *fewer* children than comparable whites did. This was especially true among the younger couples in their prime childbearing years.

At the same time, the incidence of unwanted children among the poor and near-poor in the early 1960s was estimated to be as high as 40 percent. For nonpoor couples the incidence was about 14 percent. [†] The reasons for this disparity between desires and actual reproductive performance appear to have lain less in the lack of knowledge of contraceptives than in the unavailability of effective ones. The poor who used birth control tended to use cheaper and less reliable methods than did members of the middle class. Because poor people simply could not afford the more effective contraceptives, and because no family planning information or services were provided through welfare health services until the late 1960s, most low-income people were until then deprived of effective methods of birth control.

Between 1965 and 1970, fertility among the poor and near-poor declined by 21 percent, doubtless due in part to the new services that by 1970 were reaching an estimated 1.5 million women. The greatest fertility decline occurred among nonwhite women below the poverty level. As family planning services have expanded, nonwhite fertility has continued to drop rapidly.

Despite the tendency of black militants to regard the provision of birth control information and services to the poor as a policy of "genocide" against blacks, and although the potential for abuse exists, it should be emphasized that the government's present program is basically intended to benefit the poor, and poor children in particular. In this connection it is unfortunate that the government chose to label its policy as a "population control" measure, which it is not; rather it was a logical and long overdue extension both of the family planning movement and of the welfare program.

Fears of discrimination have been aroused in areas where middle-class social workers of people operating birth control clinics in poor neighborhoods have put pressure on women to accept birth control services. There have also been cases of black women being sterilized without informed consent, and laws have been proposed for compulsory sterilization of welfare mothers. Hence black fears of genocide are not altogether unfounded. The recent decline in black fertility, however, may have defused much of the white prejudice against "black welfare mothers." The best way to avoid either the appearance or the actuality of discrimination in administration of birth control services is to have the services administered by residents of the same neighborhoods they serve as far as possible.

Although many middle-class Americans favor population control for others, especially the poor, they must realize that it is really their own excessive reproduction that accounts for most of the U.S. population growth rate. Furthermore, the middle class and the wealthy are responsible for the high rate of consumption and pollution, which are the most obvious symptoms of overpopulation in the United States.

---

extreme degree. This trend could be expected to have many undesirable social consequences (one has been the school-busing controversy). Central cities are being economically strangled and abandoned, while industry and members of the taxpaying middle class flee to the suburbs. But some social scientists have advanced the notion that, rather than being the cause of our social problems, maldistribution and migration might be symptoms of a deeper, more general malady. [30]

Population maldistribution is different from, although related to, the problem of absolute growth, and it demands a different set of solutions. Nevertheless, the distribution situation would certainly be exacerbated by a continuation of rapid population growth.

Unfortunately, the proposal to create new cities has several drawbacks. The scale of the project alone is dismaying. New cities would have to be built at the improbable rate of one the size of Spokane (Figure 13-2), Washington, *per month* until the end of the century just in order to absorb the population growth that in the late 1960s was projected for that period. In order to provide space alone for that many more people, the United States would have to sacrifice substantial amounts of land now in agricultural production. Three hundred Spokanes would occupy about 10 million acres, which is equivalent to the land producing the entire U.S. cotton crop. Wasteland or grazing land could be used instead, but most people would not find such areas desirable places to live, and shortage of water might also be a limiting factor.

Furthermore, new cities would not necessarily reduce pollution; rather, they would provide additional foci of environmental deterioration. Thus the net effect on *total* environmental impact nationwide, aside from redistributing it, would be beneficial only if careful planning were used to minimize commuting and other destructive activities in the new communities.

Peter Morrison of the Rand Corporation has pointed out several social and economic disadvantages of new cities. [31] The first difficulty is the enormous cost of building each new city, including the creation of a solid economic base to attract immigrants, in competition with

FIGURE 13-2 An aerial view of Spokane, Washington. If the population of the United States had continued to grow as fast as it did in the late 1960s, a city of this size would have to be built each month between 1970 and the end of the century to accommodate the additions to the population. (Photo courtesy of Spokane Chamber of Commerce.)

older cities. The populations of new cities, unless controlled by explicit resettling policies, might be even more homogenous than that of today's suburbs and would tend to be even more mobile. Thus new cities would be quite unstable and would tend to intensify, rather than relieve, the problems of social segregation.

Morrison suggested that a better solution to distribution problems would be to revitalize existing cities and form policies that encouraged migration in desired directions. People who move to new areas are usually attracted to better job opportunities or higher wages. Most go where they already have friends or relatives, a factor that militates against the successful establishment of new cities. Most migration in the United States occurs between urban areas; relatively few people now move from rural to urban areas. Such policies as local tax situations that encourage or discourage the development of industries, and differences among states in welfare benefits have considerable potential influence on migration.

Since passage of the *Population Act* in 1970, the government has encouraged the development of new

[30]Peter Morrison, *Urban growth, new cities, and the population problem*.
[31]Ibid ; U.S. Commission on Population Growth, *Population and the American future*, vol. 5.

cities by providing funds and guaranteeing loans to developers. Some new communities have been developed within old cities -- Roosevelt Island in New York and Cedar-Riverside in Minneapolis, for example -- but most are built some distance from older centers. The new community program was plagued with funding problems in the early 1970s, partly because of President Nixon's penchant for impoundment of funds, and partly because of HUD's fondness for red tape and failure to come through with promised technical and planning assistance or aid in starting transportation and school systems. Despite these obstacles, several new towns have come into being. The best of them incorporate housing for all income levels and try to attract minority groups. At least one new town, Woodlands, Texas, was planned by ecological architect Ian McHarg with an eye to preserving the local forest and recycling the water supply. [32]

The issue of new cities has faded somewhat since 1970, possibly because it has become increasingly difficult just to finance the maintenance of existing cities and suburbs, without taking on the even greater burden of building new ones. Another limiting factor may have been the 1973/ 1974 energy crisis, which starkly illuminated many of the faults of today's settlement and commuting patterns. Lowering population growth rates and some abatement of internal migration may also have caused politicians to view the need as less urgent than it seemed a few years earlier. Nevertheless, the problem remains of accomodating the tens of millions of people who will be added to the U.S. population by the end of the century.

In addition, the numerous social difficulties caused by present and past movements of people must be solved and efforts made to prevent their being intensified in the future. Between 1950 and 1970, one American in five moved each year, about 22 percent of these to a different state. Disproportionate numbers of the people who move are young couples in their twenties and their children. The destructive effects of such mobility on people and on communities have been vividly described by Vance Packard. [33] People are not inclined to develop loyalty or civic concern toward a town in which they feel themselves temporary residents. The community thereby loses potential support from many of its most active and talented citizens. High mobility may be hardest on children. When children cannot establish community roots, it is not surprising that they grow up alienated from older generations and from society at large.

As a result of undirected migration since World War II, many urban areas in the United States have experienced severe problems. Some cities have grown enormously while others have lost population. Peter Morrison has described the demographic effects of rapid growth on one city, San Jose, California, which tripled its population between 1950 and 1970, and population decline on another, St. Louis, Missouri. [34] San Jose's mostly young, extremely mobile population provides the advantages of a highly flexible job market and a low rate of dependency (retirees and jobless poor). But the city's population has grown almost faster than urban services such as

sewers, schools, and streets could be provided for it. No time was available for planning; developers put up houses wherever land was available. In the early 1970s, San Jose looked at itself and was appalled: a classic example of unplanned urban sprawl -- "slurbia" it is called in the vernacular.

St. Louis, by contrast, is an acute example of central city decay. The central city's population declined by 17 percent during the 1960s, while the surrounding suburbs grew by 29 percent. Those who moved out were predominantly young families, leaving behind a rising proportion of aging and retired people and disadvantaged minorities, especially blacks. High and middleincome families, both black and white, departed for suburbs or other cities, leaving the city of St. Louis to support a high proportion of low-income people on an inadequate tax base.

One approach to ameliorating the problems of overburdened cities is to encourage people to return to rural areas and small towns and cities. Such a policy, however, might require considerable revamping of American agricultural and industrial employment systems, as well as of local welfare policies that inadvertently stimulate migration from rural areas to cities. Such explicit policy

[34]Urban growth and decline: San Jose and St. Louis in the 1960s. Another recent study, in which many of the economic, social and environmental effects of unplanned urban growth are examined, is Irving Hoch , *City size effects, trends, and policies*.

changes, although there are many powerful arguments in their favor, have only begun to appear, and those have come mainly from the private sector as business firms relocated in smaller cities and towns. There has been considerable discussion of reorganizing welfare policies on a federal standard so that no locality will provide more attractive benefits than any other, but to date the discussion has not been turned into action.

Even without policy changes, however, a reversal of the centuries-long trend toward urbanization in the U.S. may now have occurred spontaneously. [35] Fed up with the growing disadvantages of life in large cities -- rising crime rates and declining levels of services and amenities -- millions of Americans have moved from cities to rural areas and small towns. A surprisingly large number of them have taken up farming, but with varied success. Some of this back-to-the-farm movement derives from the earlier hippie movement and from a growing desire among young, well-educated people for a more selfsufficient, independent way of life than is possible in a large city. Eventually, this change in life-style and personal goals may influence large companies and the government to develop policies that encourage decentralization and discourage unnecessary mobility.

Policies and Practices in Other Developed Countries

Explicit population policies are the exception rather than the rule in most developed countries. [36] Where laws affecting demographic trends have existed, they have generally been indirect, most commonly regulating or prohibiting abortion or the distribution of contraceptive information and materials. As in the United States, most such laws until recently have been pronatalist in intent. Nevertheless, a predominant social trend throughout the twentieth century has been the growth in acceptance of the idea of family limitation.

Canada. Canada's population policies have generally followed the same lines as those in the United States, with the exception that family allowances -- small allotments to subsidize support of children -- have been provided for decades. Prohibitions on distribution of contraceptive devices or information were repealed in 1969, and soon afterwards a government family planning program was launched. Regulation of abortion was also liberalized somewhat in 1969, but the new law has been applied very conservatively. Easy access to abortion is by no means a reality in Canada. [37]

The Canadian birth rate is slightly higher (15.7 in 1975) than that of the United States and has also been dropping rapidly. A major factor in Canadian population growth has been immigration, which in the 1960s made up about one-third of the nation's annual growth. In the early 1970s immigration increased as fertility declined. Traditionally liberal immigration policies are currently being reevaluated with a view to tightening restrictions and reducing the inflow. [38]

Western Europe. Western European countries generally have no official population policies other than pronatalist policies left over from before World War II when birth rates were very low. [39] Many of these countries still have family allowances to help support children in large families. Predominantly Catholic European countries still banned or restricted contraceptives and abortion as late as the 1970s.

In Europe, widespread practice of coitus interruptus has been given the major credit for lowering birth rates during the nineteenth and early twentieth centuries, with illegal abortion also playing an important role. In most of Western Europe by the 1970s, coitus interruptus and the condom were still the most used contraceptive methods, followed by the pill and the rhythm method. Among Western European countries, only in England and Scandinavia are other contraceptive devices as well known and readily available as they are in the United States. The condom is still the most commonly used device, however, and withdrawal is much more widely practiced than it is in America. However, use of the pill is increasing. [40]

[39]Much of the information on current policies comes from Richard C. Schroeder , *Policies on population around the world*.
[40]Norman B. Ryder, *The family in developed countries*.

Sweden is an exception among European countries in that it has had an official population policy since the 1930s. This policy provided for sex education (including birth control) in schools, permitted abortion in some circumstances, and offered family planning services as part of the national health organization. In addition, Sweden was the first country to have a program to assist other family planning programs abroad.

England, since 1974, has provided contraceptives and abortions through its National Health Service, and Parliament has begun discussion of developing an antinatalist policy. England also provides some family planning assistance to LDCs, mostly its former colonies.

Even though birth control has been illegal to some degree in most Catholic countries, late marriage, high rates of illegal abortion, and the use of withdrawal and the rhythm method have helped keep birth rates down. Planned parenthood groups have long existed in France, Belgium, and the Netherlands in a quasi-legal status, but until recently they were hampered by laws restricting the dissemination of information and materials. When France legalized contraceptives in the late 1960s, family allowances were also increased. Birth control devices are still entirely illegal in Ireland, although a movement for change has begun. They are also essentially illegal in Spain and Portugal. Italy has legalized the pill for "medical purposes" (presumably to combat the extremely high illegal abortion rate -- see next section), and condoms are available "for disease prevention." In 1971, Italian laws prohibiting the dissemination of birth control information were declared unconstitutional, thus opening the way for much greater access to contraceptives. In 1975 a new law authorized local governments to establish "family centers" to counsel citizens on family matters, including family planning. [41]

Immigration policies are also being reevaluated in several Western European countries. In recent years, much of the labor force (11 percent in France and West Germany, 7 percent in Britain, and 37 percent in Switzerland) has been composed of "guest workers" -temporary migrants from poorer countries in Southern Europe, Northern and Central Africa, and the Middle East. [42] The worldwide economic recession in the mid1970s led to an intensification of the controversy, especially in Switzerland, which has twice considered outright deportation of all immigrants (thus throwing many firms, dependent on migrants, into panic). [43] So far such proposals have been rejected, although many social problems continue to be blamed on the foreigners in most of these countries. Should economic conditions seriously worsen, such xenophobic policies could be revived and even implemented.

Eastern Europe and USSR. In the Soviet Union and Eastern European countries, the substantial postWorld War II declines in fertility were achieved mostly through abortion, which is provided by their national health services. These countries now also distribute contraceptives, including the pill, partly in an effort to reduce the abortion rate. This policy seems to be succeeding in some countries, although abortion is still the primary means of birth control. Discouragement of early marriage, an emphasis on training, education, and the full outside employment of women also undoubtedly strongly encourage the small family trend.

Extremely low birth rates in Eastern European countries have caused a reversion to more pronatalist policies -- especially a tightening of abortion laws -- in response, apparently, to concern about future labor supplies. Communist ideology officially calls for a pronatalist

posture, and the Soviet government periodically exhorts its people to have more children. Interestingly, however, the Russians have cautiously begun to recommend lower fertility in rapidly growing less developed countries. [44]

Oceania. Australia and New Zealand have historically regarded themselves as underpopulated. Consequently their policies until recently were pronatalist and pro-immigration. These policies are currently being reevaluated as the public becomes aware of the world population problem, and neither country any longer

subsidizes the transport costs of immigrants. A Zero Population Growth movement was founded in Australia in 1971. As former English colonies, both countries have long had family planning organizations and access to contraceptives. Their birth rates have been well within the usual DC range, although their growth rates have been inflated by high immigration rates. As in many European countries and the United States, the birth rates in Australia and New Zealand have been declining toward replacement levels since 1970.

Japan. Japan, the only fully industrialized country in Asia, reduced its birth rate rapidly to DC levels after World War II, largely by legalizing abortion. A policy of encouraging the use of contraceptives has since reduced the abortion rate without changing the birth rate, even though Japan has been slow to legalize the pill and the IUD. The social policy on population, which was promoted through massive educational and communications programs in the 1950s, very strongly discouraged having a family with more than 2 children. Accordingly, fertility has been close to replacement levels since then. Around 1970, alarmed by an apparent labor shortage, Japanese industry began campaigning for more births. The crude birth rate rose during the mid-1970s, but the rise was essentially an artifact of age composition; the postwar baby boom children born before legalized abortion halved the birth rate (1945-1955) were then in their twenties -- the prime reproductive years. The recession of 1974 effectively seems to have silenced the campaign for higher fertility. At the same time, the growth of both environmental concern and a women's liberation movement in Japan may have a fertilityreducing effect in future years.

Abortion

The most controversial method of birth control without question is abortion, which is surrounded by legal, ethical, and moral dilemmas. Despite this, it seems to have been practiced in all societies and is probably still the commonest method of birth control today, especially in LDCs. Until the early 1970s, abortion was illegal in most countries, including the United States (see

Box 13-4). Disapproval of the practice probably originated with the Judeo-Christian ethic, yet it was not made illegal until the nineteenth century. Then it was outlawed on the grounds that it was dangerous to the mother -which it was before sterile techniques were developed. When performed today under appropriate medical circumstances by a qualified physician, however, abortion is much safer than a full-term pregnancy. The death rate in the United States for legal abortion in the first trimester (first three months of pregnancy) is less than 2 in 100,000. For second-trimester abortions the rate rises to 12 per 100,000, still only half the maternal death rate for childbirth. [45]

But danger to the mother escalates alarmingly when the abortion is illegal, as it still is in many countries. The amount of risk varies according to the circumstances, which may range from self-inducement with a knitting needle or, almost equally hazardous, unsterile help from untrained people, to reasonably safe treatment by a physician in a hotel or clandestine clinic.

Changing abortion laws in DCs. Before abortion was legalized in the United States, bungled illegal abortions were the greatest single cause of maternal deaths, accounting for a conservatively estimated 300 or more deaths per year. [46] They still are in those countries where abortion remains illegal or not yet widely available. In Italy, for example, contraceptives were entirely banned until 1971, and the illegal abortion rate at that time was estimated to be equal to or higher than the birth rate -- 800,000 to 1.5 million per year -- and costing as many as 3000 lives per year. [47] Most of these abortions were self-inflicted or accomplished with the aid of a sympathetic but untrained friend. When a woman with a hemorrhage was brought to a hospital, she was automatically given tetanus and penicillin shots. She never

[45] Family planning perspectives, Abortion-related deaths down 40 percent. . . . See also C. Tietze and S. Lewit, *Legal abortion*, whose figures for abortion mortality, derived from the U.S. and the U.K., show abortion mortality risks approximately equal to childbirth between the twelfth and sixteenth weeks, and somewhat higher thereafter. Both sources agree on the low risks of first trimester abortions.

BOX 13-4 Abortion in the United States

Before 1967, abortion was illegal in the United States except when the mother's life was endangered by continuing the pregnancy. Only six years later, the situation had been completely reversed, legally if not everywhere in practice. Yet the change was not effected overnight; it was the result of changed public attitudes in response to a growing reform movement.

By the end of 1970, 15 of the 50 states had at least partially moderated their abortion laws. Most of these new laws permitted abortion only in cases where bearing the child presented a grave risk to the mental or physical health of the mother, where the pregnancy was a result of incest or rape,

and where (except in California) there was a substantial likelihood that the child would be physically or mentally defective. To obtain an abortion, a woman usually had to submit her case to a hospital reviewing board of physicians, a time-consuming and expensive process. Although the laws ostensibly were relaxed to reduce the problem of illegal abortions, hospital boards at first interpreted the changes in the law so conservatively that they had little effect. The number of illegal abortions per year in the U.S. during the 1960s has been variously estimated at between 200,000 and 2 million, with 1 million being the most often quoted figure. This amounted to more than one abortion for every four births. At that time, there were estimated to be 120,000 illegal abortions per year in California; in the first year after the passage of California's "liberalized" law there were just over 2,000 legal ones. The figures were similar for the other states.

In 1970 Hawaii, Alaska, and New York passed new laws essentially permitting abortion on request, and Washington State legalized abortion on request not by legislation but by referendum. Meanwhile, several other states began to interpret their relatively restrictive laws much more liberally, and the legal abortion rate rose considerably. These changes in state laws were preceded and accompanied by an erosion of public opposition to abortion. Table 13-1 shows the changes in public disapproval as revealed in polls taken between 1962 and 1969 for demographer Judith Blake.

A poll taken early in 1970 asked: Should an abortion be available to any woman who requests one? In apparent contradiction to the earlier opinions, more than half of those interviewed said yes. Although most respondents did not approve of abortion except for the more serious reasons, the majority apparently felt that mothers should be free to make their own decisions.

Continuing this trend, a poll conducted in 1971 for the U.S. Commission on Population Growth and the American Future found that 50 percent of the adults interviewed felt that the decision to have an abortion should be made by the woman and her doctor, 41 percent would permit abortions under certain circumstances, and only 6 percent opposed abortion under all circumstances. Similar results have been obtained in subsequent surveys. [a]

In January 1973, the U.S. Supreme Court announced its decision on an abortion case which in effect legalized abortion on request nationwide, at least for the first trimester (13 weeks), with restrictions on the second trimester being permitted in the interest of protecting women's health. Only in the last ten weeks of pregnancy, (when the child, if born, had a chance of survival) the court ruled, could states prohibit abortion except "to preserve the life or health of the mother." [b]

The number of legal abortions performed in 1972 (before the Supreme Court decision) was about 600,000; in 1975 it was about one million -- approximately the estimated previous number of illegal abortions. At least two-thirds of these abortions probably would have been obtained illegally if legal abortions had been unavailable. [c] Nor had illegal abortions entirely disappeared -- 25 of the 47 deaths from abortions in 1973 were from illegal ones (those not performed under proper medical supervision) -- although the incidence of such deaths clearly had been drastically reduced by 1975. [d]

Yet, three years after the Supreme Court decision, there were still large discrepancies from one region to another and between medical facilities in providing abortion services. An ongoing

national study by the Guttmacher Institute [e] in 1975 concluded that between 260,000 and 770,000 women who needed abortions in 1975-20 to 40 percent of the women in need --

were still unable to obtain them. More than half of all abortions after 1973 were carried out in specialized clinics, while public hospitals (which provide most medical services to the poor) were lagging even behind private hospitals in providing services. Only one in five U.S. public hospitals reported performing any abortions in 1975. Thus in many areas it was substantially more difficult for poor women to obtain abortions than for middle-class or wealthy women, even though government funds were available to cover the costs. Teenagers, who account for about onethird of the need for abortion services and for a large and growing portion of the illegitimate birth rate, also seem to have poor access to safe abortions. Finally, abortion services were found to be generally less available in the southern and central regions of the U.S. than on either coast.

In the United States, the majority of abortion recipients are young and/or unmarried. There is some debate over the degree to which legal abortion has affected American fertility overall, but it seems to have had a significant effect on the rate of illegitimate births. In 1971 reductions in illegitimate births in states with legal abortion ranged as high as 19 percent, while in most states without legal abortion they continued to increase. [f] Following the Supreme Court decision, the rising rate of illegitimacy halted briefly, then began again. The rise was accounted for by an increase in teenage pregnancy.

There is no evidence that abortion has replaced contraceptives to any significant degree, despite the apprehensions of antiabortion groups on this score. Most women seeking abortion have a history of little or no contraceptive practice, and many are essentially ignorant of other means of birth control. Those who return for subsequent abortions have been found to be still ignorant of facts of reproduction, using contraceptives improperly, or to have been poorly guided by their physicians. [g]

Paralleling the trend toward liberalized abortion policies in the U.S. has been the growth of right-to-life groups who are adamantly opposed to abortion. These groups have lobbied actively against reform of state laws and, since the Supreme Court decision, have tried to persuade Congress to reimpose sanctions against abortion through Constitutional amendments. Under their pressure, Congress has removed funds for

abortion services from Foreign Aid grants to LDCs. In 1976, Congress also passed a law forbidding federal assistance for abortions in the U.S., a move that denies these services to lowincome women -- precisely the group whose chances for a decent and productive life are most likely to be jeopardized by an unwanted child. Whether the courts will consider such a discriminatory law constitutional is another question. Right-to-life groups have also played a part in harassing clinics, hospitals, and other organizations that provide abortion. This activity often embarrasses clients and possibly has also discouraged other institutions from providing abortion services.

Action by right-to-life groups in Boston resulted in the trial and conviction for manslaughter in early 1975 of physician Kenneth Edelin following a late-term abortion (about 20 weeks). The prosecution maintained that the fetus might have survived if given life-supporting treatment. (The conviction was overturned in December 1976 by the Massachusetts Supreme Judicial Court.) [h] The consequence of the original verdict nevertheless was to discourage late secondtrimester abortions (31 states already had laws against them except to protect the mother's life or health; in most states abortion by choice was available only through the 20th week). Unfortunately, this change also will affect mainly the poor and/or very young women, who through ignorance or fear are more likely to delay seeking an abortion until the second trimester.

In 1976, a Right-to-Life political party was formed, centering on the abortion issue. Its candidate, Ellen McCormack, entered primaries in several states, but never succeeded in winning more than 5 percent of the vote. Most Americans, it appears, accept the present legal situation at least as the lesser of evils.

admitted having had an abortion; under Italian law she had committed a crime and could be sent to prison. Some years ago in a confidential survey of 4000 married women of all classes, all admitted to having had abortions, most of them many times. [48]

A movement is now underway to loosen the laws against abortion in Italy, following the limited legalization of the pill in 1971, despite strong opposition from the Vatican and conservative political elements. The Italian constitutional court in early 1975 ruled that abortion is legal if doctors determine that the pregnancy threatens the physical or mental health of the mother.

Before the 1970s, variations on the Italian abortion tragedy prevailed in several other Western European countries. In France, contraceptives were available but not openly, and the illegal abortion rate and attendant rates of death and injury nearly matched those of Italy. In late 1974, abortion was legalized in France, shortly after a new law was passed greatly increasing public access to contraceptive devices and information.

Similar reversals have occurred in many DCs since 1965. West Germany, Denmark, and Austria legalized abortion on request between 1973 and 1975, although its status in Germany was changed by a court decision and remains to be reestablished by legislation. In 1975 Sweden changed its already moderately liberal law to allow abortion up to the twelfth week as a decision for the woman alone to make. Finland, Norway, and Iceland have long had liberal policies, but they fall short of availability on request. Laws against abortion in Greece and the Netherlands have been neither observed nor enforced and soon may be reversed. The same was formerly true of Switzerland, which in 1975 moved to liberalize its abortion laws. Great Britain has in effect permitted abortion on request since 1967. Spain, Portugal, Belgium, and Ireland still had very restrictive laws in 1976. [49]

In most of Eastern Europe, abortion has long been legal and usually subsidized by the state. Abortion has been legal since 1920 in the Soviet Union, and in most Eastern European countries (except Albania) since the 1950s. Abortion brought birth rates so low that Bulgaria, Czechoslovakia, and Hungary tightened their regulations in 1973. Romania severely restricted access to abortion in 1966, with the result that its birth rate virtually doubled the following year. Since then, the birth rate has declined toward the 1966 level, indicating an increase in illegal abortions. The rates of hospitalizations and deaths from abortion complications have also risen substantially. Meanwhile the huge cohort of children born in 1967 has caused havoc in the Romanian school systems. [50]

Canada has relaxed its abortion law somewhat; practice is considerably short of "on request," but widely liberal interpretation of the new law might make it close. Canadians denied abortions often go to the United States. Australia is moving toward liberal policies, although access varies by state. New Zealand remains restrictive, but discussion of change has begun.

Abortion in LDCs. The tragedy of illegal abortion thus is rapidly becoming a thing of the past in most of the developed world, but change is coming more slowly in much of the less developed world. In some countries the problem of illegal abortion is increasing because the need for abortion seems to be rising. There are important exceptions, particularly China, where abortion has been liberally provided by medical services since 1957. In India abortion was legalized in 1972, but there was so little publicity that even large segments of the medical community as well as the public were unaware of it for the first few years. For those who knew, high costs and excessive red tape were effective deterrents. For at least the first three years, the number of legal abortions was extremely low (41,000 in the first five months), while the number of nonmedical illegal abortions was appallingly high (at least 4 million a year). [51]

Elsewhere in Asia, abortion has been legalized in South Korea (1973), North Vietnam (1971), Hong Kong (1972), and Singapore (1969, further liberalized in 1974). Abortion is firmly illegal in Taiwan, but apparently easily obtainable from medical practitioners, nonetheless. Laws are still restrictive in Indonesia, Pakistan, Sri Lanka, Thailand, and the Philippines, but there are signs

[50] Teitze and Murstein, *Induced abortion*; Charles F. Westoff, *The populations of the developed countries*.

[51] "The abortion dilemma", *Atlas*, November 1974, pp. 16-18.

that they may soon be changed in several of these countries.

In the Middle East and North Africa, laws are generally very restrictive, except in Tunisia (which has had abortion on request in the first trimester since 1973) and Cyprus, which partially liberalized its law in 1974. Israel's tough anti-abortion law was weakened by a challenging court decision in 1952 and is seldom observed today. Abortions reportedly are also available through medical facilities in Egypt despite a strict anti-abortion law.

In Africa south of the Sahara, abortion is generally prohibited (the exceptions being Zambia since 1972 and some liberalization in South Africa). Ironically, these restrictive laws are holdovers from colonial times; they are not rooted in local culture. [52]

Abortion is still illegal in most Latin American countries, although laws have recently been relaxed to permit it under certain circumstances in El Salvador, Guatemala, Mexico, Panama, Brazil, Chile, Argentina, Ecuador, and Peru. Abortion essentially on request is available only in Uruguay and Cuba (since 1968 in both cases).

Illegal abortion is rampant in Latin America. Contraceptives are legally available in most Latin American countries, but in practice only accessible to the rich. The illiterate poor, who make up a large share of the Latin American population are generally unaware of the existence of birth

control other than by ancient folk methods, and could not afford modern methods even if they knew of them. There are exceptions where governments and volunteer organizations such as Planned Parenthood have established free birth control clinics (see next section). Although these can help, they as yet reach only a small fraction of the population, mainly in cities. In rural areas where hunger and malnutrition are often widespread, a failure of primitive birth control methods leaves women with no alternative but to practice equally crude forms of abortion.

In the 1960s bungled abortions were estimated to account for more than 40 percent of hospital admissions in Santiago, Chile. In that country, an estimated onethird of all pregnancies end in abortion. In Mexico, 400,000 women per year are treated in hospitals for illegal abortions; the abortion rate is conservatively estimated at one-fourth the birth rate. [53] For South America as a whole, some authorities believe that onefourth of all pregnancies end in abortion; others estimate that abortions outnumber births.

Liberalizing abortion laws in various countries has been shown to have two important effects. The first is a very large decline in maternal deaths and morbidity (illness) associated with illegal abortion. The degree of reduction of death and illness depends on the degree of change in the law, the previous rate of illegal abortions, and how they were usually performed (i.e., self-inflicted under unsanitary circumstances or performed clandestinely by medical personnel). The number of annual abortion deaths in the U.S. dropped from over 150 per year before 1970 to 47 (25 of which were from illegal abortions) in 1973; in England the decline was from 60 before 1968 to 11 in 1974. [54] Declines in many European countries and LDCs, where crude self-abortion has been more common, will probably be much greater. Conversely, the number of deaths in Romania, where abortion regulations were tightened, rose from about 70 in 1965 to over 370 in 1971. [55]

The other result of liberalizing abortion laws is to provide such services safely to low-income women. When abortion is illegal, the rich can usually still obtain a safe illegal procedure or can afford to travel to another country where legal abortion is available. The poor have no such options; it is they who suffer most either from the burdens of large families or from dangerously unsafe illegal abortions.

The moral issue. The greatest obstacles to freely available, medically safe abortion in many developed countries and in Latin America are the Roman Catholic Church and other religious groups that consider abortion immoral. The crux of the Catholic argument is that the embryo is, from the moment of conception, a complete individual with a soul. In the Catholic view, induced abortion amounts to murder. Some Catholics also oppose

[55] Ibid.

abortion on the grounds that it will encourage promiscuity -- exactly the same reason given in Japan for banning the pill and the IUD. There is no evidence to support either point of view on promiscuity, but, even if there were an increase, it would seem a small price to pay for a chance to ameliorate the mass misery of unwanted pregnancies -- especially since the main ostensible reason for social disapproval of promiscuity is the production of unwanted children.

Many Protestant theologians hold that the time when a child acquires a soul is unknown and perhaps unimportant. They see no difficulty in establishing it at the time of "quickening," when movements of the fetus first become discernible to the mother; or at the time, around 28 weeks, when the infant, if prematurely born, might survive outside its mother's body. To them, the evil of abortion is far outweighed by the evil of bringing into the world an unwanted child under less than ideal circumstances.

To a biologist the question of when life begins for a human child is almost meaningless, since life is continuous and has been since it first began on Earth several billion years ago. The precursors of the egg and sperm cells that create the next generation have been present in the parents since they were embryos themselves. To most biologists, an embryo or a fetus is no more a complete human being than a blueprint is a complete building. [55a] The fetus, given the opportunity to develop properly before birth, and given the essential early socializing experiences and sufficient nourishing food during the crucial early years after birth, will ultimately develop into a human being. Where any of these is lacking, the resultant individual will be deficient in some respect. From this point of view, a fetus is only a *potential* human being, with no particular rights. Historically, the law has dated most rights and privileges from the moment of birth, and legal scholars generally agree that a fetus is not a "person" within the meaning of the U.S. Constitution until it is born and living independent of its mother.

From the standpoint of a terminated fetus, it makes no difference whether the mother had an induced or a spontaneous abortion. On the other hand, it subsequently makes a great deal of difference to the child if an abortion is denied and the mother, contrary to her wishes, is forced to devote her body and life to the production and care of the child. In Sweden, a study was made to determine what eventually happened to children born to mothers whose requests for abortions had been turned down. When compared to a group of children from similar backgrounds who had been wanted, more than twice as many of the unwanted youngsters grew up in undesirable circumstances (illegitimate, in broken homes, or in institutions); more than twice as many had records of delinquency, or were deemed unfit for military service; almost twice as many had needed psychiatric care; and nearly five times as many had been on public assistance during their teens. [56]

In a 1975 study in Czechoslovakia, nine-year old children whose mothers had been denied abortions were compared with carefully matched "controls." [57] The unwanted children tended to have more problems of health and social adjustment and to perform less well in school than did their peers who had been wanted. Further, it appeared that the disadvantages of being unwanted -- initially, at least -- affected boys more strongly than girls.

There seems little doubt that the forced bearing of unwanted children has undesirable consequences not only for the children and their families, but for society as well, apart from the

problems of overpopulation. The latter factor, however, adds further urgency to the need for alleviating the other situations. An abortion is clearly preferable to adding one more child to an overburdened family or an overburdened society, where the chances that it will realize its full potential are slight. The argument that a decision is being made for an unborn person who "has no say" is often raised by those opposing abortion. But unthinking actions of the very same people help to commit future unheard generations to misery and early death on an overcrowded planet. One can also challenge the notion that older men, be they medical doctors, legislators, or celibate clergymen, have the right to make decisions whose consequences are borne largely by young women and their families.

There are those who claim that free access to abortion

[55a]Garrett Hardin, *Abortion--compulsory pregnancy?*

[56]Lars Huldt, *Outcome of pregnancy when legal abortion is readily available*.

[57]Z. Dytrych, et al., *Children born to women denied abortion*.

will lead to genocide. It is hard to see how this could happen if the decision is left to the mother. A mother who takes the moral view that abortion is equivalent to murder is free to bear her child. If she cannot care for it, placement for adoption is still possible in most societies.

Few people would claim that abortion is preferable to contraception, not only because of moral questions, but also because the risk of subsequent health problems for the mother may be greater. Death rates for firsttrimester, medically supervised abortions are a fraction of those for pregnancy and childbirth but considerably higher in later months. [58] Large and rapidly growing numbers of people nevertheless feel that abortion is vastly preferable to the births of unwanted children, especially in an overpopulated world. Until more effective forms of contraception than now exist are developed, and until people become more conscientious in use of contraceptives, abortion will remain a needed back-up method of birth control when contraception fails.

Attitudes on abortion have changed in most countries in recent years, and they can reasonably be expected to change more in the future. The female part of the world's population has long since cast its silent vote. Every year over one million women in the United States, and an estimated 30 to 55 million more elsewhere, have made their desires abundantly clear by seeking and obtaining abortions. Until the 1970s, these women were forced to seek their abortions more often than not in the face of their societies' disapproval and of very real dangers and difficulties. Millions still must do so.

There is little question that legalized abortion can contribute to a reduction in birth rates. Wherever liberal laws have been enacted, they have been followed by lowered fertility. Longstanding evidence is available from Japan and Eastern Europe, where abortion was the primary effective form of birth control available for some years after liberalization, and where the decline in fertility was substantial. The extent of decline is bound to be related to the availability of other birth control methods; but even in the United States and England, where

contraceptives have been widely available, the decline in fertility after reversal of abortion policies was significant.

According to at least one study, availability of abortion (legal or illegal) may be necessary in order for a population to reach and maintain fertility near replacement level, given current contraceptive technology and patterns of sexual behavior. [59] Liberalization of abortion policies in those countries where it is still largely or entirely illegal is therefore justifiable both on humanitarian and health grounds and as an aid to population control.

POPULATION POLICIES IN LESS DEVELOPED NATIONS

In response to rising alarm during the 1950s over the population explosion in less developed countries, both private and governmental organizations in the United States and other nations began to be involved in population research and overseas family planning programs. First among these, naturally, was the International Planned Parenthood Federation, which grew out of the established national groups. By 1975 there were Planned Parenthood organizations in 84 countries, supported by their own governments, private donations, government grants from developed countries, or some combination of these sources. [60]

Various other private and governmental organizations followed Planned Parenthood into the field, including the Ford and Rockefeller Foundations, the Population Council, the U.S. Agency for International development (AID), and agencies of several other DC governments. International organizations such as the World Bank and various UN agencies, particularly the UN Fund for Population Activities, had joined by 1970. The 1960s brought a great proliferation of family planning programs in LDCs, which were assisted or administered by one or another of these groups. Most assistance from DCs was provided through one of the international or private organizations. In 1960 some $2 million was spent by developed countries (and the U.S. was not then among them) to assist LDC family planning programs; by 1974

the amount was over $200 million, more than half of it from USAID. Yet less than two percent of all foreign assistance goes to LDC family planning programs, and most LDCs allot less than one percent of their budgets to it. [61]

During the 1960s national family planning programs were established in some 25 LDCs, while 17 other governments began supporting or assisting the activities of private Planned Parenthood organizations. The early 1970s saw a further proliferation of these programs until by 1975, 34 less developed countries officially favored the reduction of population growth, and 32 more supported family planning activities for other reasons. Some 55 additional LDCs still did not support family planning, or in a few cases opposed it. But the combined 1973 populations of the

pro-family planning countries were nearly 2.5 billion, whereas the total combined population of the anti-family planning nations was only about 250 million. [62] Table 13-2 shows details.

Government Policies in LDCs

So far family planning programs are the primary policies that have been brought into action against the population explosion in most LDCs. Outstanding exceptions are the People's Republic of China, [63] Indonesia, India, Pakistan, South Korea, Singapore, Tunisia, Egypt, and a few other countries where other social and economic policies have been adopted to supplement family planning. [64] However, many family planning programs have been established and are even being supported by governments for reasons other than reduction of population growth, usually to protect the health and welfare of mothers and children. Although no country has yet adopted attainment of ZPG as a goal, many have aimed at an ultimate reduction of growth rates to DC levels -around 1 percent per year or less. A few countries, by contrast, still want to increase their usually already rapid growth. Many others are beginning to reevaluate their pronatalist policies as consequences of rapid growth become increasingly evident. The following discussion sums up these various approaches by continent. [65]

Africa. Africa, an extremely diverse continent, growing at about 2.6 percent per year, includes some of the world's poorest and most rapidly growing nations. Because high mortalities, especially of infants, are also commonly found in these countries, concern over rapid growth and action to curb it have developed only relatively recently in most of them. Indeed, some African governments remain staunchly pronatalist.

The belief that more people are needed for development is common among African nations south of the Sahara. Policies in Cameroon, Malawi, and Upper Volta still frankly favor growth, while Zambia and the Malagasy Republic have only recently reversed their positions (in 1975). Concern about poorly controlled migration is greater in many of these countries than concern about high birth rates.

In general, family planning on a private basis has long been available in former African colonies of England, but not in those of such Catholic countries as France, Belgium, Spain, Italy, and Portugal. Former English colonies were among the first to establish national family planning policies, although emphasis in some cases is put on health and family welfare justifications. Kenya and Ghana have two of the oldest and strongest family planning programs in subSaharan Africa, and both have goals of reducing population growth. Interest in family planning at least for health reasons is growing in most former English colonies, although a few such as Malawi still discourage or ignore the activities of private family planning organizations. Nigeria, the most populous and one of the richest (in terms of resource endowment) African countries, was only beginning to show interest in family planning for health reasons in 1976, despite rapid growth.

[62] D. Nortman, *Population and family planning programs*, 1974 and 1975.

[63]See Edgar Snow, *Report from China-III: population care and control, for an early report on China*. More recent reports have generally confirmed that first impression: for example, Pi-Chao Chen, "China: population program at the gross roots", in *Population: perspective 1973*, H. Brown , J. Holdren, A. Sweezy, B. West, eds.

[64]Vumbaco, *Recent law and policy changes*.

[65]For country-by-country details of policies and recent demographic trends, Population Reference Bureau, *World population growth and response*, prepared with the assistance of the U.S. Agency for International Development, is invaluable. Schroeder and Vumbaco each provide useful summaries, as does the more recent D. Nortman and E. Hofstatter, *Population and family planning programs: a factbook*, 1976.

In South Africa and Rhodesia, the dominant European populations have traditionally practiced birth control. These countries are now trying to extend family planning services to their African populations. South Africa's family planning is offered through its Planned Parenthood affiliate and funded by the government; Rhodesia's services are government-supported, but operated by several private international groups.

Former French colonies have begun to relax their prohibitions to allow the commercial sale of contraceptives and to support some family planning activities. The first family planning clinics in French-speaking continental Africa have been established in Senegal, whose government is beginning to show interest in family planning. Most former French colonies, however, remain complacent about their rates of population growth. An exception is Mauritius, an island nation with one of the highest population densities in the world (see Chapter 5). Mauritius has a vigorous and comparatively successful family planning program. Since the 1950s, the growth rate has been reduced to about 2.1, despite an unusually low death rate of 7 per 1000 population.

The Portuguese colonies, Mozambique and Angola, remained pronatalist and strongly opposed to birth control until they achieved independence in 1975. Establishment of population programs must await the stabilization of the new governments.

Some North African countries have initiated family planning programs; Egypt, Tunisia, and Morocco have fairly strong, antinatalist policies. Tunisia, in particular, has ventured beyond family planning to legalize sterilization (considered immoral and against Moslem law in most Islamic countries) and abortion, to limit financial allowances for children to four per family, raise the legal marriage age, and ban polygamy. In addition, women's rights, usually very restricted in Moslem societies, are being promoted. Some other North African countries -Algeria, Libya, Mauritania -- remain pronatalist or uninterested.

Many African countries still have death rates above 20 per thousand, and some even more than 30. A number of demographers and family planning officials believe that interest in population control will remain low in those countries until the death rates have been substantially reduced, especially among infants and children. It is vitally important to change this point of view so that efforts can be made to lower birth rates *along with* death rates; that most family planning efforts have begun in African countries as a part of maternal and child health services is an encouraging sign.

Latin America. Latin America as a region, despite having some of the highest population growth rates in the world (about 2.9 percent for the entire region), has also been very reluctant to accept a need for population control. This is probably due in part to the influence of the Roman Catholic Church, but there is also a widespread belief, at least in South America, that the continent still contains vast untapped resources of land and minerals, that the answer to all problems is development, and that more people are needed for development. Latin American politicians, moreover, tend to view proposals originating in the United States for birth control with understandable suspicion. Some seem to believe the U.S. is trying to impose a new and subtle form of imperialism. [66] In some countries, this reaction has even had the effect of inhibiting the teaching of demography and family planning in universities.

Latin American economists and politicians have come to accept family planning (often referred to as "responsible parenthood") mainly on health and welfare grounds and as a means of reducing the horrendous illegal abortion rate. Some leaders are beginning to realize, however, that the galloping population growth rate is swallowing all the economic progress each year, leaving a per-capita rate of progress of zero or less. A few countries have established essentially, though not always explicitly, antinatalist policies as a result -- notably Chile, Colombia, several Caribbean countries, and all of the Central American countries. The efforts of some family planning programs in the Caribbean (mainly former British colonies) have been counted among the most successful, especially those of Barbados and Trinidad and Tobago. Birth rates have declined there since the early 1960s, and have declined as well in Chile, Colombia, Costa Rica, Nicaragua, Panama and Venezuela.

---

[66] National Academy of Sciences, *In search of population policy: views from the developing world*; *Population policy in Latin America*.

At the other extreme, Brazil and Argentina have policies generally promoting growth. Brazil does permit private family planning groups to operate, however, especially in the poverty-stricken Northeast. Argentina, having a relatively low birth rate and feeling threatened by rapidly growing Brazil, in 1974 banned dissemination of birth control information and closed family planning clinics. Since the practice of birth control is well established in the Argentine population, the action is not likely to have great effect except perhaps to raise the already high abortion rate, mostly illegal.

Asia. Asia includes over half of the human population and is growing at about 2.3 percent per year. Both mortality and birth rates are generally lower than those in Africa, and both have been declining in several countries.

Asia presents a widely varied picture in regard to population policies. At one extreme, China, India, Thailand, Indonesia, Sri Lanka, Hong Kong, Singapore, Taiwan, and South Korea are pursuing strong family planning policies, in several cases reinforced by social and economic measures, some of which are described below. All of these countries have recorded declines in birth rates, some of them quite substantial. Family planning programs have also been established

in Pakistan, Bangladesh, Nepal, Malaysia, and the Philippines, but the impact, if any, on birth rates is negligible so far.

A few rapidly growing countries, notably Cambodia and Burma, currently are pursuing pronatalist population policies, although family planning is privately available in the latter country. Other "centrally planned" countries in Southeast Asia seem to be following China's example in population policies; North Vietnam has had a family planning program for some time, which presumably was extended to South Vietnam when the nation was unified. Policies in North Korea are unknown.

Middle Eastern nations are still largely pronatalist in their outlook, with the exceptions of Turkey and Iran which have national family planning programs. Several countries, including Afghanistan, Bahrain, Cyprus, Iraq, Jordan, Lebanon, and Syria, are interested in establishing family planning services for health and welfare reasons. The remaining countries favor continued growth, although they may tolerate family planning activity in the private sector. Among these is Israel, for obvious reasons. At the furthest extreme is Saudi Arabia, which has outlawed importation of contraceptives. Nearly all Middle Eastern countries are growing rapidly with relatively high, although declining death rates.

The United Nations. For many years, the United Nations limited its participation in population policies to the gathering of demographic data. This, however, was instrumental in developing awareness of the need for population policies, especially among LDCs, whose governments often had no other information about their population growth. Since the late 1960s the UN has taken an active role in coordinating assistance for and directly participating in family planning programs of various member nations, while continuing the demographic studies. A special body, the UN Fund for Population Activities (UNFPA), advises governments on policies and programs, coordinates private donors and contributions from DC governments, and sometimes directly provides supplies, equipment, and personnel through other UN agencies.

In 1967 the UN Declaration on Social Progress and Development stated that "parents have the exclusive right to determine freely and responsibly the number and spacing of their children." [67] The statement affirmed the UN's increasing involvement in making family planning available to all peoples everywhere and contained an implicit criticism of any government policy that might deny family planning to people who wanted it. The statement has sometimes been interpreted as a stand against compulsory governmental policies to control births; however, the right to choose whether or not to have children is specifically limited to "responsible" choices. Thus, the Declaration also provides governments with the right to control irresponsible choices.

In 1974 the United Nations' World Population Conference, the first worldwide, government-participating forum on the subject, was convened in Bucharest. Publicity attending the event gave an impression of enormous disagreement among participating groups. But in fact it provided a valuable forum for an exchange of

[67] Declaration on Population, Teheran, 1968, *Studies in Family Planning*, no. 16, January, 1967.

ideas and information and seems to have stimulated interest in population problems among many less developed nations that had previously shown no interest at all. The conference is discussed in more detail later in this chapter.

Family Planning Programs

Studies conducted in LDCs when family planning programs are initiated have typically revealed that knowledge of birth control is very limited in these populations, especially outside the cities and the educated classes. The practice of birth control is even more limited. A major difficulty is that people in the LDCs generally want more children than do people in DCs, for various reasons that are discussed below in the section on *Motivation*.

Family planning programs in LDCs are usually carried out either through independent clinics or in cooperation with maternal and child health agencies, or both. In some countries, mobile units are used to carry workers and equipment to remote villages. Unlike traditional planned parenthood organizations in DCs, these programs actively recruit clients, employing specially trained field workers for this purpose and utilizing whatever forms of mass communication and promotion seem effective and appropriate. These may include pamphlets and circulars, advertisements in public transportation, billboards, radio and newspaper announcements, or plays and skits produced by traveling troupes. In India an elephant has been taken from village to village and used to pass out pamphlets and contraceptives. The primary emphasis in most programs has been on preventing the "unwanted child." Initially at least, the greatest effort has been made to reach women who already had at least three children, because they are usually most receptive to the idea of birth control. [68] The hope is that, as family planning gains acceptance, younger women with fewer children will begin to practice birth control. In countries with well-established, strong programs, this has happened.

Family planning programs generally offer a choice of birth control methods, sometimes including sterilization, although before the mid-1970s this method was only used or promoted on a large scale in India, Pakistan, and Bangladesh. The most popular method in Asia has been the IUD, although it has proven to be less ideal than it first seemed. Barely 50 percent of the women fitted with IUDs still wear them two years later. Malnutrition may contribute to this high discontinuance rate by increasing the tendency to bleed after insertion (which in turn worsens the malnutrition -- especially iron deficiency anemia). This is just one example of how conditions partly caused by overpopulation can hinder efforts to establish population control.

The use of other methods, especially the contraceptive pill, has been increasing in recent years. Some countries are now permitting distribution of the pill without prescription by family planning workers. These workers interview clients beforehand with a questionnaire designed to eliminate women whose medical histories indicate that the pill might have dangerous side effects for them. Since in most LDCs, the danger of pregnancy and childbirth are several times greater than in DCs and far outweigh the health risks of the pill, this approach seems to be working quite successfully in Thailand and Pakistan, among other countries. [69] The pill is proving considerably more successful than the IUD had been in both countries.

Distribution of condoms has become an important element of the family planning program in India, Pakistan, and several other countries. Other traditional methods, such as diaphragms, jellies and foams, are also increasingly being offered. Abortion was widely available only in China among LDCs before the mid-1970s, but if recent changes in abortion laws are implemented, and if abortion services are integrated into the family planning structure, the situation could change dramatically in several countries.

Clinic staffs include doctors (usually gynecologists), nurses, midwives, and occasionally social workers. A few programs also employ anthropologists to advise the staff

---

[68]Most of the information on how family planning programs are organized comes from various issues of *Studies in Family Planning* and other periodicals published by The Population Council, Inc. For a general overview, see W. B. Watson and R. J. Lapham (eds.), *Family planning programs: world review 1974*; or Population Reference Bureau, *World population growth and response*. In addition, the July/August 1974 issue of *Unesco Courier* contained several articles on family planning programs and population policies in LDCs.

[69]Freedman and Berelson, *The record of family planning programs*; Milton Viorst, *Population control: Pakistan tries a major new experiment*.

personnel on the best approach to villagers. Midwives are often used as field workers and/or medical workers in clinics, although some problems have resulted from employing them. Midwives sometimes see family planning as a threat to their incomes from child delivery, as well as from illegal abortion, in which they may be profitably involved. Some of the newer programs are recruiting teachers or other respected community leaders to act as distributors of contraceptives, usually condoms or pills.

There is, of course, a great deal of variation among programs in terms of services offered, means of distributing materials and information, recruitment methods, and so forth. The approaches that have been used in India, and their results under difficult circumstances, are described in Box 13-5. India's family planning program, although derived from Western aid programs, is by no means typical. Even though many of the problems it faces are shared by other LDCs, in some respects, including the sheer magnitude and diversity of the population itself, it is essentially unique. Indonesia, Pakistan, and Bangladesh present some of the same logistic difficulties as India, but each of those has a population only a fraction as large. China's population is larger than India's, but possibly less diverse, and its political organization allows policies to be imposed from the top (see Box 13-6 for a detailed discussion of China's population policies). Its totally indigenous population program is different in several important respects from that of any other country.

Besides offering contraceptives, family planning programs in many LDCs, like the older organizations in DCs, provide counseling services for marriage, parenthood, and child spacing, and assistance for subfertile and sterile couples. Women's discussion groups are often organized in villages to interest wives in birth control. Advice on nutrition and child care may be included in the discussions, partly because these subjects may attract women to the family planning

program, and partly because dissemination of this information contributes to the program's child welfare goals.

Some hope of increased effectiveness in reaching younger women early in their reproductive lives lies in introducing family planning to them immediately after the birth of their first child. Pilot studies of this approach in both DCs and LDCs have brought promising results, although to be effective it may require special personnel in the hospital who do nothing else. Attempts to have hospital staff members add to their other duties the teaching of family planning to maternity patients have often failed, however. Doctors and nurses in such hospitals are generally overworked already; and they often have not been particularly motivated in favor of family planning. Moreover, in the poorest LDCs (where birth rates are apt to be highest) children are seldom born in a hospital except among the wealthy urban classes, who are likely to be using birth control already.

With the exception of India (and perhaps China), no LDC had an official family planning program prior to 1960, and most have been established since 1965. Because they are so new, it is difficult to evaluate the potential value of most of these programs.

For example, one of the most active among newer family planning programs is Indonesia's (1968), which quickly outran the World Bank's estimates of what could be accomplished within three years after the organization was set up. [70] By 1974 about 32 percent of women of reproductive age in Bali and perhaps a similar proportion in East Java were using contraceptives, mostly as a result of the program's efforts. Nationwide, about 14 percent were using birth control. Many other LDCs have been unable to match that performance even in a considerably longer period of time. It is still too early for results to show in the nation's birth rate, however, and whether the early momentum in recruitment can be maintained remains to be seen.

Some of the earlier and stronger family planning programs have made considerable progress in terms of reaching a large proportion of the reproductive population. [71] Around 1973, for instance, contraceptive users as a percentage of women of reproductive age had exceeded 60 percent in Singapore, not far below the rate commonly found in developed countries. In Taiwan and Hong Kong, acceptance rates were well over 50 percent, and in South Korea and Colombia they had reached 30 percent.

BOX 13-5 India: A History of Frustration

Once poverty caused overpopulation, but it is now overpopulation that is causing poverty.

-- Karan Singh

Minister for Health and Family Planning in India, 1976

India's family planning program began in 1952, when the country had a population of over 360 million and was growing at about 2 percent per year. For the first decade the program was not strongly supported, but in 1965 it was overhauled and a better organized and supported effort ensued. But the modest reduction in the birth rate between 1965 and 1975 from 41 per thousand population to about 35 (according to Indian demographers) was matched by the decline in mortality. In 1975 the population was over 600 million and still growing at close to 2 percent. If the birth rate cannot be further reduced substantially, (and the death rate does not rise), the population will reach one billion by the end of the century. [a]

India's family planning measures have included the establishment of clinics (associated with maternal health facilities where possible), temporary camps, and mobile units (Figure 13-3), all accompanied by an active education campaign both within and outside the schools to promote small families. By 1975 there were some 1900 urban family planning centers, 5000 rural centers, and 33,000 subcenters throughout the country. Vasectomy and the IUD have been the most used methods, although female sterilization, condoms, and other contraceptives have been made increasingly available. Men who accept vasectomies, and any individual who persuades a man to have one, are paid small fees. Railway stations have been used as vasectomy clinics in place of hospitals, partly because they attract large numbers of people and partly because Indians traditionally regard hospitals as a place to die. In addition, a program of active research and development of new contraceptive methods, including investigations of folk methods and reversible vasectomy, has been carried on.

During the 1960s India ran into some problems with its family planning policies, particularly in rural areas. Aside from the monumental logistic difficulty of taking family planning to every one of 500,000 villages, a good deal of overt resistance has been met in some places, which has even led occasionally to riots and the destruction of camps and mobile units. This resistance resulted in part from the existence of three active medical traditions in India besides Western medicine -- ayurvedic, unani, and homeopathic. The family planning program originally was implemented only through Western medicine, a circumstance that naturally resulted in resentment and opposition from the others. [b] Resistance has also come from religious and ethnic minority groups who may have perceived family planning as discrimination. Perhaps most fundamental, family planning may be perceived by rural peasants as directly contrary to their economic interests (see section on motivation). In the late 1960s, this opposition showed itself in a drop in vasectomy and contraceptive acceptance rates. [c]

In an effort to expand the effectiveness of the program, India began experimenting with "family planning festivals." In one district during July 1971, over 60,000 vasectomies were performed at one festival. IUDS, condoms, and female sterilizations were also available. Greater than usual incentive payments and gifts were offered both to recipients and to recruiters. The festival also included entertainment and cultural events. There was a great deal of publicity, and entertainers toured the surrounding countryside beforehand to attract people to the festival. Cooperation and support were secured from local voluntary organizations, government officials, professional

groups, and labor unions, which probably contributed much to the success of the campaign. [d] Altogether, by 1975 some 14 million Indian people had been sterilized, many of them in such special festival camps.

Expansion of family planning activities in

India was forced to a halt in late 1973 and 1974 by a governmental financial crisis, which was followed by the oil crisis that quadrupled India's costs for vitally needed oil imports. The family planning budget for 1974 was cut to half the originally planned amount. In response to consternation expressed by other nations over that action, some of the funds were later restored, but only enough to allow the continuation of already established activities.

In late 1974, possibly spurred by the example of China's apparent success and by India's deteriorating food situation (Chapter 7), India announced another reorganization of the family planning program. [e] Funding for the five-year period 1974-1979 was increased more than 80 percent over 1969-1974. It was planned to broaden the availability of Copper-T IUDS, oral contraceptives, and abortion, none of which had been generally available through the program before. Educational and motivational efforts also were to be increased. In addition, family planning workers were being retrained as general health workers in an effort to raise public health standards throughout the country while also providing information and the means of birth control. The corps of family-planning/health workers is projected to expand from 80,000 to 130,000 over time. This is clearly a worthwhile plan on all counts, provided the health services are adequate and the birth control drive is not diluted by the additional duties of the workers.

In early 1976, India took an even more radical step in its population policies, requiring government employees in New Delhi with more than two children to be sterilized and denying public housing and other benefits. Incentives were provided for those who restricted their families to no more than two children. The federal government also encouraged states to enact similar compulsory laws. The state of Punjab passed a law imposing a prison sentence, a fine, or mandatory sterilization for couples who bear a third or subsequent child, with some broad exceptions. Maharashtra state passed a similar law affecting

couples with more than three children, and West Bengal was considering such a law. [f]

The compulsory sterilization policy proved to be a major factor in the defeat of Indira Gandhi's government in March 1977. The new government's Minister of Health and Family Planning promptly announced a reversal of the policy and a return to emphasis on contraceptives rather than sterilization in the family planning program. BOX 13-6 China: An Apparent Success Story

Any brief treatment of Chinese society is difficult and necessarily contains elements of overgeneralization. First of all, the huge geographical expanse and the vastness of the population -- nearly a billion people -- are difficult to envision. Second, the Chinese people possess a cultural diversity possibly as rich as that of Europe, and even older traditions. Finally, it seems that there is no overall, systematic keeping of vital statistics and population figures in China, and those statistics that do exist are not readily available to outsiders. The Chinese are traditionally xenophobic, and the Western intrusion of the last century and a quarter -- from the Opium Wars through the United States debacle in Vietnam and Soviet pressure on northern Chinese borders -- have only heightened this traditional aloofness. The available information is therefore fragmentary and has to some extent been filtered by a highly centralized and autocratic regime. Still, the accounts of foreign travellers in China and the release of official statements and figures allow some conclusions to be drawn about the nature of population policy in the People's Republic. [a]

Superficially, the expressed population policies of the People's Republic of China seem slightly schizophrenic. Official rhetoric preached abroad roundly condemns Malthusian ideas: "The poor countries have not always been poor. Nor are they poor because they have too many people. They are poor because they are plundered and exploited by imperialism." [b] The same article goes on to blame "relative overpopulation and widespread poverty" in the United States and the Soviet Union on "ruthless oppression and exploitation which the superpowers practice at home."

But, despite assertions that there is no such thing as overpopulation, China admits to having a policy of "planned population growth," with this rationale:

We do not believe in anarchy in material production, and we do not believe in anarchy in human reproduction. Man must control nature, and he must also control his numbers. . . .

We believe China's policy benefits many aspects of life-national construction, the emancipation of women, protection of mothers and women and children, proper bringing up of the young, better health for the people and prosperity for the nation. It is, in other words, in the interests of the masses of the people. [c]

In recent years, as China has begun to open up to the outside world, it has become increasingly clear not only that "birth planning," as it is called, is seriously advocated and supported by the government, but that it has begun to reap results. Exactly how successful the policy has been overall is impossible to say because there are no reliable nationwide population statistics. The last reasonably comprehensive census was conducted in 1953 (when a total mainland population of about 583 million was found), and estimates of vital rates since then are basically guesswork. [d] Hence the estimates of total population in 1975 range from below 800 million to 962 million. [e] China specialist Leo Orleans has proposed a set of estimates and projections of China's population from 1954 to 1980, and his arguments in support of them are convincing. He suggests that the 1975 population was about 850 million, with a birth rate of 27 per thousand, a death rate of 12 per thousand, and a natural increase of 1.5 percent. These figures are slightly above those of the UN.

China's efforts to curb population growth began in the 1950s following the release of the census results and a period of heated discussions of the pros and cons of birth control. An organized campaign implemented by the Ministry of Public Health was launched in 1957 but then was suspended in 1958 during the Great Leap Forward, an intensive effort at economic development. The period 1959-1961 was one of food shortage and economic crises, and, although established birth control clinics continued to

[d] Leo A. Orleans, *China: Population in the People's Republic*. This is an excellent source for historical background, although otherwise somewhat out of date.

[e] Orleans, China's population figures: Can the contradictions be resolved? The lowest are based on casual statements by Chinese officials at the UN; the highest are from the *World Population Estimates* of the Environmental Fund, which bases its estimates on the figures of John Aird, a demographer in the U.S. Department of Commerce Foreign Demographic Analysis Division.

function, there was no official encouragement for their use.

While China was recovering from this crisis period, the government again began advocating "birth planning" to protect the health of mothers and children. An important part of this campaign was promotion of late marriage (23 to 25 for women, 25 to 28 for men) and the two-child family spaced by 3 to 5 years. [f] Both abortion and sterilization were legal from the start, but the middle 1960s were a period of active expansion of facilities (along with expansion of health care in general) and experimentation in improved techniques. It was then that the Chinese developed the vacuum technique for abortion, which has made the procedure much safer than before, and which has since been adopted around the world. Active research was also carried out on simplified sterilization procedures. It appears, for instance, that the Chinese may have been the first to do female sterilizations with very small incisions. [g]

China has all along manufactured all its own contraceptive devices and pharmaceuticals, unlike other LDCs. The latest invention is the "paper pill," sheets of water-soluble paper impregnated with oral contraceptives, which are easy to transport, store, and distribute. [h] Each sheet contains a month's supply of "pills" in perforated squares that dissolve in the mouth when eaten. This development is expected to increase use of oral contraceptives considerably, especially in remote rural areas where the pills have been less accepted than in the cities.

Virtually every method of birth control is being actively used in China: sterilization, abortion, the combined steroid pill and the progestin mini-pill, long-term injections, IUDs (the Chinese developed their own, a stainless steel ring), condoms, diaphragms, foams, and jellies.

The various forms of birth control have long been available to the people in the major cities and their suburbs. During the 1960s, health care, including birth control services, was increasingly extended to more remote rural areas. As an indication of the success of the health care programs, the death rate for the entire country is estimated to have dropped from nearly 35 per 1000 population in 1949 to about 17 per 1000 in 1970 [i] and perhaps 13 in 1974. [j] Infant mortality, which fairly accurately reflects levels of both health care and nutrition, is thought to have been between 20 and 30 per 1000 births in 1974. [k] In some urban communes (which apparently do keep careful demographic statistics), the crude death rate is 5 or less, and an infant mortality rate of 8.8 per 1000 live births has been claimed for the city of Shanghai. [l]

China's unique health care system, together with greatly improved distribution of the food supply, can claim credit for this remarkable change. At the time of the Revolution, a grossly inadequate corps of trained medical personnel existed, mainly concentrated in the large cities. While actively training thousands of doctors, paramedics, and nurses and establishing hospitals and health centers in smaller cities, the Chinese also promptly tackled sanitation and hygiene at the grass-roots level through educational campaigns.

More recently, selected people have been given four to six months' basic medical training and assigned part-time to care for basic health needs in their production brigades. These individuals are called "native doctors" in the cities and "barefoot doctors" in the country. Their responsibilities include giving injections and innoculations, administering first aid and simple treatments for diseases, supervising sanitation measures, teaching hygiene in schools, and distributing contraceptive materials. For medical treatment beyond their competence (including abortions and sterilizations), the barefoot doctors refer patients to the nearest regional hospital. Barefoot doctors in turn are assisted by part-time volunteer health aides, usually housewives, whom they train themselves. [m]

It now appears that China is attempting to upgrade the quality of grass-roots health care by sending fully trained medical personnel from city hospitals on rotation to rural health centers, where, among other things, they provide additional training for local health workers. Some barefoot doctors have thereby become qualified to do abortions, IUD insertions, and steriliza-

Box 13-6 (Continued)

tions, as well as other minor operations. [n]

Both child bearing and birth control are fully supported and helped in China. Paid maternity leave, time off for breast-feeding, free nursery care, and all needed medical attention are provided for mothers. Paid leave is also given for abortion, sterilization, and IUD insertions, and all birth control services are essentially free.

While the means of birth control are provided through the health care system in China, primary responsibility for motivating couples to make use of them rests with the Revolutionary Committee (or governing council) of the production brigade or commune. Usually one member of the committee is the "responsible member" for birth planning. [o] In rural areas, "women's cadres" -married women with children, who are known and respected by their neighbors -- carry contraceptives and the pro-birth control message house to house. [p]

In some of the cities, low birth rates have been so enthusiastically adopted as a goal that neighborhoods collectively decide how many births will be allowed each year and award the privilege of having babies to "deserving couples." [q] Priority is given to newlyweds, then to couples with only one child who have waited the favored period of time for the second birth. [r] The result has been phenomenally low birth rates for these neighborhoods, ranging from 4 to 7 per 1000 population. The center city of Shanghai reportedly had a 1972 birth rate of 6.4, while that for the city plus suburbs was 10.8. [s] The 1972 birth rate for Peking was reported by Joe Wray to have been about 14 per 1000 population; Myers placed it at 18.8 for city and suburbs combined.

Joe Wray has speculated that these low rates may have been helped by a relatively low proportion of women in their child-bearing years. Given the recent Chinese policy of sending urban young people to rural areas to work, this may be so, even though China's demographic history would indicate a relatively large and growing proportion of people in their teens and twenties for the country as a whole by 1975.

Exiling young people "temporarily" to rural communes probably was done for political reasons. Large numbers of urban youth are a potential source of insurgent trouble, especially if insufficient jobs are available. Scattering the young people in the countryside could effectively defuse that threat. Moreover, the relatively well-educated city youth could help spread the

ideology of the central government to remote rural areas. But it appears that the policy may also have had demographic effects. Most of the city children are not happy down on the farm; consequently, they are reluctant to marry, settle, and raise families there. Nor are rural young people eager to marry the sophisticated city people with their strange ways. [t]

The official Chinese position on birth planning -- an ideal of late marriage and a small, well-spaced family of two children -- appears to have been overwhelmingly accepted in cities and is rapidly gaining acceptance in rural areas, according to reports from foreign visitors. [u] The prevailing attitude is that early marriage and having more than two children are prime examples of irresponsible behavior. Nevertheless, there is still resistance from older generations, especially mothers-in-law, who by tradition have long wielded considerable power within families and apparently still do.

Besides official encouragement to limit families, there are other incentives built into the social and economic system as well. Emancipation of women and their incorporation as full working members of society was an early, important goal of the Revolution. It has apparently been realized to a great extent, especially among younger women, and undoubtedly exerts a powerful influence on childbearing.

Pi-Chao Chen has pointed out disincentives to family limitation in the per capita grain allowance, which augments a family's supply when a child is added, and in the addition of another worker (preferably a boy who will remain in the family) to contribute to family income. [v] But it has also been observed that, even though another worker may help increase a family's total income, that income must still be divided among all family members. Additional members reduce the share available per person. [w] Furthermore, since

compulsory primary education is rapidly becoming the rule in China, children's productivity is inevitably deferred at least until the teenage years.

While there is no question whatever about the Chinese leadership's position on birth planning, coercion does not appear to be a part of the program beyond the extensive use of peer pressure

and the dissemination of propaganda on all levels. There were reports of curtailed maternal benefits, reduced grain rations, and discriminatory housing and employment assignments for parents of three or more children in some areas during the 1960s, but these measures seem to have been largely abandoned. Possibly they aroused more resentment than cooperation and were found to be less than beneficial to the children.

By the mid- 1970s, China's far-reaching population program evidently had been extended to the far corners of the nation -- no mean trick in itself. What the results have been is impossible to assess with accuracy, but it is becoming increasingly clear that they are significant indeed. The remarkable vital rates prevailing in major cities have already been cited, but those of rural communes for which data exist, while higher than the cities', show significant reductions from pre-revolutionary levels (birth rate about 45, death rate 34 to 40, infant mortality above 200). [x] Reported birth rates for rural districts in the early 1970s range from as low as 14 in an area near Shanghai [y] to 20-24 in communes near Peking [z] and some others in more remote provinces. [aa] These areas generally report very low death rates also. Levels of contraceptive usage in urban and rural areas are compared in Figure 13-4. Certainly the communes visited by outsiders are among the most successful by Chinese standards, and so their birth and death rates should not be taken as representative of the entire country. But they may represent the leading edge of an established trend. That the policy has been so successful in many areas, especially where it is long established, indicates that similar success can be expected elsewhere in time.

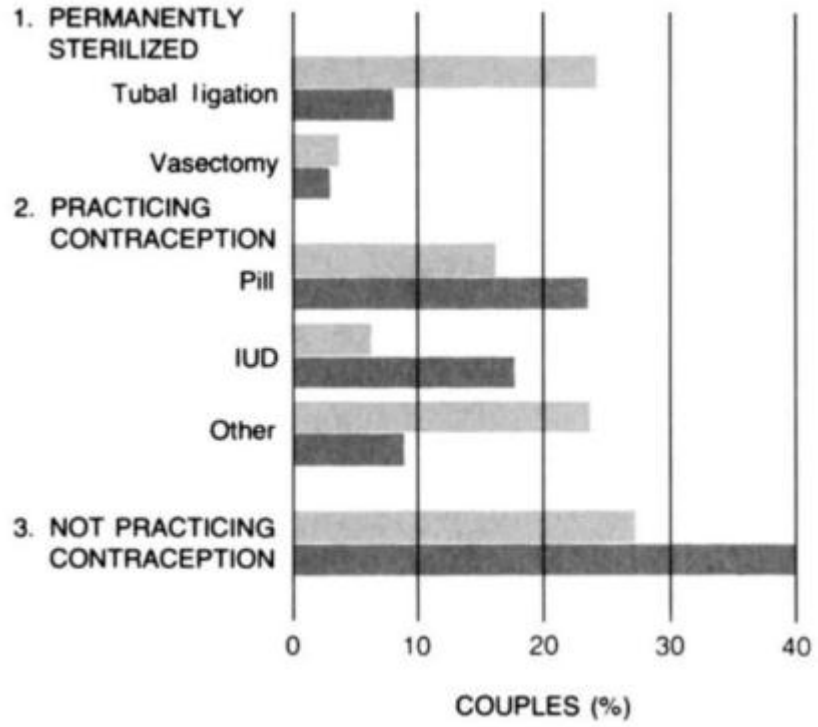

FIGURE 13-4
Contraceptive practices in an urban area (light grey) and in a rural area (dark grey) in China are compared; the urban sample is from the city of Hangchow, a provincial capital, and the rural sample is from a commune outside Peking. Sterilization is nearly three times commoner in the urban than in the rural sample, and substantially fewer rural males use contraceptives. The bias

seems to be reflected in the difference between urban and rural birth rates: below 10 per 1000 in some urban areas and above 20 per 1000 in some rural ones. (From Sidel and Sidel, 1974.)

If available estimates of vital rates for all of China reflect reality, there has already been a substantial reduction in birth and death rates. Norman Myers of the FAO quotes birth rate estimates for large cities of between 10 and 19 per 1000 population, for medium-sized cities, 14 to 23, and for rural areas 20 to 35. He put the national 1974 birth rate at 29 and the death rate at 13, giving a natural increase of 1.6 percent per year. Comparison of these estimates with those of other Asian nations at similar levels of development is striking, to say the least. And no doubt other less developed countries -- and perhaps some developed countries as well -- can learn a great deal from the Chinese experience. [bb]

*Data on birth and growth rate goals that have been set by the national family planning programs are from Berelson, *Studies in family planning*, no. 39 (supp.), 1969. Where two numbers are given under goals, the first is the starting point.

**Data for 1976 birth and growth rates are from the Population Reference Bureau, Inc.

†The target population is the number of married couples in the reproductive ages (15-44). The protected population refers to the percentage of the target population which is sterilized or using some form of contraception, whether provided by a government program or through private services.
Data from Dorothy Nortman, Population and family planning: a factbook.

††Natural increase in Trinidad and Tobago is close to 2.0. The difference is accounted for by massive emigration.

Many other countries, on the other hand, even with relatively long-established family planning programs, have made discouragingly little progress toward fulfilling their own short-term goals of birth rate and growth rate reduction (Table 13-3), some of which may however have been unrealistically optimistic. In seeking reasons for the apparent lack of success of many family planning programs, the people associated with them have naturally looked to drawbacks of the programs themselves or to ways in which governments implement them. [72] Some correlation between the availability of a variety of birth control methods--as one indication of a strong program--and decline in birth rate can be seen in Table 134. A surprising number of programs rely on only one or two contraceptive methods, and relatively few make use of two of the most effective methods--abortion and sterilization.

The strength of the family planning program, however, is clearly not the whole story. Taiwan and South Korea, for instance, have shown considerable drops in birth rates since their relatively early and strong programs were initiated, but birth rates in both countries had begun to decline even before then, indicating a preexisting desire for smaller families in much of the population.

How much of the recent decline is directly due to the family planning program is practically impossible to determine, as the administrators of the programs themselves admit. Presumably, the activities of the family planning program facilitated and accelerated the developing trend toward smaller families.

Recently, several other small less developed nations-Hong Kong, Singapore, Costa Rica, Barbados, Trinidad and Tobago, Fiji, and Mauritius--have dramatically reduced their birth rates (see Table 13-4). No doubt the relatively strong family planning programs in many of these nations can claim some of the credit for the rapid changes, but other social and economic factors ap-

parently have played a precipitating role in changing people's attitudes toward family size. What these external factors may be has begun to emerge from comparisons of the few countries in which birth rates have dropped with others that have shown no significant reductions. These socioeconomic influences are discussed later in this chapter.

Studies in various countries with different levels of development and different population densities have indicated that people tend to have the number of children they say they want, although reproductive ideals, of course, may change through time. [73] Surveys have shown that the average number of children wanted per family in recent decades has varied from 2.0 to 3.3 in European countries; in the U.S. it was about 3.3 during the early 1960s and approximately 2.3 in the early 1970s.

By contrast, the average in most LDCs ranges between 3.5 and 5.5, and higher fertility reflects these desires. People in LDCs also seem to prefer overshooting to

[73]Freedman and Berelson, *The record of family planning programs*; Freedman and Hermalin,

undershooting their ideals, given higher infant and child mortality rates. Because of those rates, replacement fertility in those countries would be about 2.8 children per woman--somewhat above the 2.1 needed in DCs where mortality is lower. Obviously, therefore, wherever average desired family sizes are above three, population growth in LDCs cannot be stopped merely by preventing "unwanted" births, although that is certainly a desirable first step.

MOTIVATION

Unquestionably the single most important factor in a country's reproductive rate is the motivation of the people toward the regulation of family size. The strength of the desire for a small family is critical. If a couple is determined not to have more than two children, they usually will not, regardless of whether or not there is a birth control clinic down the street. Conversely, if motivation is weak, the practice of birth control is likely to be a sometime thing--although the motivation may grow with the number of children in the family.

The overriding importance of motivation is made clear by the example of Europe, where the family planning movement has had relatively little influence, particularly in Catholic countries. The continent as a whole has the lowest birth rates of any major region in the world, and many European countries have had low birth rates for at least two generations. The population of Europe is growing at considerably less than 1 percent per year (0.6 percent); only Albania and Iceland have growth rates that exceed 1.2 percent. Moreover, several countries--both Germanies, Malta, Portugal, and Luxembourg--now have achieved negative growth rates; that is, their populations are now declining very slightly or fluctuating around a zero rate of growth.

This remarkable record has been accomplished largely in the absence of modern contraceptives. The dissemination of both information and devices until recently has been completely banned in several countries and seriously restricted in others. Yet the birth rates have been just as low in these countries as in neighboring countries where information and devices were generally available and in moderately wide use. *Coitus interruptus* is known and practiced everywhere, especially where contraceptives have been restricted, and is generally backed up by abortion, either legal or illegal, depending on the country. In one way or another, most Europeans have managed to avoid having children they do not want, and today they commonly want no more than two.

Motivation in LDCs

In many less developed countries, the opposite situation obtains: people say they want larger families and often end up with even more children than they had originally desired. [74] Although people may show interest in birth control, when modern contraceptives are offered they are frequently spurned. Why haven't Indian peasants, for instance, eagerly accepted birth control devices? One explanation is that, among other things, to do so may be directly against the peasants' economic interests as they perceive them.

Many observers have theorized that prospective parents rationally base their family size decisions on the advantages and disadvantages of children. In developed countries, the costs of raising, supporting, and educating each child are considerable, competing for other desired purchasable "goods" and for time in which the mother could earn income. The benefits, on the other hand, are largely confined to the emotional rewards and satisfaction of the desire for immortality. Economic returns come only after the children are adults, if ever.

Among the poor in traditional societies, the cost/benefit structure is quite different: children contribute to the family economy from an early age and represent old-age insurance to boot. Costs are comparatively small, limited to food (on a farm the children help produce the food), clothing, and shelter. [75]

Another factor often cited as an important influence on birth rates is the infant mortality rate. [76] In many poor countries such as India, Pakistan, Bangladesh, and much of tropical Africa, infant mortality is still very high. It is

[74]Freedman and Hermalin, *Do statements about desired family size predict fertility?*

[75]This view is almost conventional wisdom in development literature. A good description and references to other works on the subject can be found in James E. Kocher, *Rural development, income distribution, and fertility decline*, p. 60.

[76]Harald Frederiksen, *Feedback in economic and demographic transition*.

estimated at about 140 per 1000 live births in India nationwide, for instance, and doubtless is even higher among the rural poor. [77] Preschool child mortality also is high. In these countries, therefore, one out of every four or five children dies by the age of five. For the poorer half of the population, the number may be closer to one out of three. Hence, to have reasonable assurance that at least one son -- and preferably two for extra security -will survive to adulthood, couples must bear an average of six children.

Some family planning specialists have suggested that couples who have lost children may overcompensate and bear more than one child to replace each one lost. [78] The connection between high fertility (especially closely spaced births) and child mortality does not seem to be generally recognized in illiterate poor populations (Box 13-7).

Indian writer Mahmood Mamdani has described the situation in the village of Manupur in the state of Punjab, site of an early experimental attempt to introduce family planning which had disappointing results. [79] The problem of land fragmentation is a major one at Manupur -large families mean that many sons eventually must divide up the family farm -- but such fragmentation has been going on for a long time. The potential user of birth control is very often a victim of land fragmentation, struggling to wrest a living from a piece or pieces of land marginal in size or quality or both. But according to Mamdani, the problem of future fragmentation is seen as just that -- a *future* problem. The task of making a living and assuring support in old age is a pressing one for today.

In the struggle to make ends meet today, sons (and to a lesser extent daughters) are considered a necessity. Without sons a farmer may be unable to farm his land; he must rent it out, which is a considerably less desirable alternative. Sons either work the farm in place of hired laborers, or they work in the city and, if they can, send money back to the farm. In either case they may add substantially to the family's income, but only marginally to costs.

There were, of course, other factors that militated against small families in Manupur, among them a strong pronatalistic tradition. In India a woman is judged primarily by her fertility: "May you have many sons" is a standard greeting to a woman. Barrenness is considered a disgrace, a bad omen. Some villagers believe that a barren wife is a "witch" who can place children and others under evil spells. The childless woman is barred from attending childbirths and from many celebrations. She is likely to be divorced or to be the reason for her husband to take an additional wife.

Small wonder, then, according to Mamdani, that Manupur villagers, who politely told the family planning workers they would practice birth control and accepted devices, seldom ever used them. Those who did were merely replacing inefficient methods with better ones. There was some decline in the birth rate (from 40 to 35 per thousand between 1957 and 1968) during the birth control campaign, but Mamdani claimed that it was mainly due to a rise in the age of marriage associated with technological and social change in the village. Only the Brahmins, whose social dominance and way of life were being undermined by those changes and who traditionally value education and scorn farming and other physical labor, saw much advantage in family planning. Of the majority of villagers, ". . . in Manupur, those who had few resources responded to adversity not by decreasing their numbers but by increasing them. In numbers they found security and the only opportunity for prosperity." [80]

Some critics have wondered, however, why the villagers should have been less polite and more candid to Mamdani, a relatively casual visitor from the city, than to the missionary medical workers who lived in the area for several years and ministered to the village families. [81] The authors of the Khanna study were quite aware of the social and traditional barriers to contraceptive acceptance and the need for social and economic change to

BOX 13-7 Fertility, Maternal and Infant Health, and Mother's Milk

Typifying the interconnections between rapid population growth, and poverty, poor nutrition, and poor health is the infant mortality-fertility syndrome. [a] It is widely believed that an important factor motivating couples living in poverty -- especially in LDCs -- to have large families is high infant and preschool child mortality. [b] But it seems to be less widely recognized that high fertility itself contributes to these high death rates.

Studies in many countries, both developed and less developed, for decades have shown that generally the risks of stillbirth, prematurity, and infant and child mortality increase with each birth after the fourth. The exception is the first birth, which is attended by a higher risk (presumably for biological reasons). [c] Rapid childbearing also leads to higher mortality, especially if the interval between births is less than a year. In this case, all the children in the family may be at risk: older siblings because of the general burden of supporting the larger family; the next youngest child who may have been weaned too early; and the new baby because of the mother's burdens, which may include nutritional stress.

That children in large families are relatively disadvantaged, even in comfortably-off families in DCs where nutrition and medical services are quite adequate, is fairly well known. Not only are infant and child death rates higher in large families, but the children tend to be less healthy, smaller for their ages, and to perform less well in school and on IQ tests. These tendencies also increase with birth order. [d]

Early and late childbearing also result in higher infant mortality rates. In both developed and less developed countries, mortality ranges from 75 to 100 percent higher for infants born to women under 20 than to women aged 25-29. In most poor countries, 10 to 20 percent of all births are to teenagers. In the United States 20 percent of births are to teenagers. This is a high proportion for a developed country, and it may be a factor in the relatively high infant mortality rate in the U.S. Childbearing after 34 also carries increasing risks for the children; the danger here tends to be proportionally greater in poor countries where general health conditions are poorer and medical facilities are less adequate.

Less well studied, but clearly established is the relationship of maternal deaths to fertility. Again excepting first births, the mother's risks of death and serious disease or injury from pregnancy and childbirth increase with each birth after the third and with the shortness of birth interval. [e] Higher rates of maternal mortality and complications are

precede a change in attitudes. What the study (and Mamdani's critique) showed was the large and growing discrepancy between the peasants' perceptions of advantageous reproductive behavior and where their real advantages lay.

Land fragmentation by now is acute, but employment in a city is also an increasingly less viable alternative (see Chapter 15 on the problem of unemployment in India and other LDCS). When the current crop of babies reaches adulthood, this problem is likely to be much worse. As better-off rural couples limit their families, they are in a position to consolidate their affluence; the multiplying poor are losing ground.

The situation described by Mamdani and the attendant attitudes are by no means confined to Indian peasants; they prevail among the rural poor throughout Asia, Africa, and Latin America with minor differences. Tradition, usually reinforced by religious teaching, is strongly pronatalist, and interference with the reproductive process is commonly considered immoral. [81a] Furthermore, displaced -- whether temporarily or permanently -- urban migrants generally share the

---

[81a] Alan Sweezy believes that the influence of traditional morals relating to reproduction is often overlooked or underestimated by social scientists trying to explain resistance to family planning, perhaps in large part because it is difficult to quantify. (Sweezy, *Economic development and fertility change*.)

also associated with childbearing before the age of 20 and after 30, especially after 34.

These trends are consistent in all countries and social levels where they have been studied. The main difference is that among the poorer classes in poor countries, the mortality rates are many times higher than in developed countries. Maternal mortality ranges up to 50 times higher in some LDCs than in DCs. The usually cited reasons are the prevalence of malnutrition, poor sanitation and health practices, and the lack of medical services in LDCS. Malnutrition, which most affects children under five, is endemic in many LDCs (see Chapter 7 for a fuller discussion). In recent years this has been exacerbated by the trend toward abandonment of breastfeeding in favor of commercial formulas. Most poor families cannot afford to use formulas in full strength, and the lack of sanitary facilities, including safe water, makes their use extremely hazardous. Adequate medical care, also, is unavailable to the poor in most LDCs, especially in rural areas.

To these fairly obvious factors in high infant, child, and maternal mortalities in LDCs could be added high fertility and early and late childbearing. About 40 percent of women in LDCs have four or more children, whereas in DCs only 6 or 7 percent do. In poor countries women commonly marry and begin having children as young as 15 or 16, and they often continue bearing children up to the age of 40 or more. The irony that reducing high infant and child mortalities in LDCs (and thereby increasing population growth) may be a necessary prerequisite to acceptance of family limitation among the poor (apart from being imperative on humanitarian grounds) has often been remarked on; the idea that the use of birth control may be one important means of saving the lives of children and mothers is only beginning to be widely appreciated.

Improving nutrition is another vitally important way of saving lives and improving the health, well-being, and productivity of people in general. One of the best -- and least costly -- ways to improve nutrition of infants is to encourage breast-feeding, especially for the first six months of life. Here again, the relationship is not a simple one, for breast-feeding tends to suppress fertility in the mother and thus extends the important interval between births. [f] Lactation does not reliably prevent conception, however. Providing contraceptives to a nursing mother therefore can ensure that premature weaning is not forced by the occurrence of another pregnancy, which would endanger the lives of both children and of the mother. The abandonment of breast-feeding leads both to higher birth rates and higher infant mortalities; reinstating it as a general practice would tend to reduce both, and might as a result lead to lower family-size aspirations as well.

economic and social viewpoint of their rural cousins -and their reproductive goals. Many urban poor families grow their own food in their shantytowns, and children are valued as helpers in the gardens and as income earners in the streets. In such situations, wherever children are perceived (correctly or not) by their parents more as blessings than burdens, it is probable that large families will continue to prevail.

The impact of colonialism. Anthropologist Mildred Dickeman has suggested that a personal, short-term perception of the advantage of a large family has come to take precedence over the long-term disadvantage to society because of a "breakdown in social integration," which she regards as "a failure in one of the most fundamental ecological functions of human social systems." [82] This social breakdown, she claims, was caused by Western colonialism, which interfered with traditional societies' perceptions of their food supplies, resource limitations, and demographic situations.

Nearly all societies encompass seemingly contradictory attitudes and ideologies regarding natality. Dickeman discusses the practice of infanticide in particular, but such phenomena as birth control, abortion, and marriage

---

[82] Dickeman, *Infanticide*.

[f] Buchanan, *Breast-feeding -- aid to infant health and fertility control*.

customs are also subject to varying attitudes and mores. These conflicting attitudes allow societies to fine-tune their responses to external changes without having to change the basic ideological structure itself. Thus, when overpopulation threatens food supplies, for example, antinatalist behavior can be encouraged, and when epidemics or war have decimated a population, antinatalism can again be discouraged. Pronatalist attitudes are very strong in traditional societies because through most of humanity's evolutionary history they have been needed to maintain populations and to allow a moderate amount of growth when warranted.

The sudden introduction of death control, Western morality, and access to communications and other resources, as Western technology impinged upon the underdeveloped world in the wake of the colonial era and World War II, disrupted social perceptions of the consequences of high birth rates in those areas. The impact was characterized by "rapid and fluctuating changes in

agricultural productivity, labor demand, urbanization, emigration, and military expansion, often coupled with introduced epidemic disease." [83] Because most of these disturbed societies have adopted Western ideology, their traditional methods of controlling population have been abandoned and unfortunately replaced by less efficient and less desirable ones, mainly selfinduced abortion and disguised infanticide through neglect, abuse, and even starvation. Dickeman concludes that the world population can only be controlled when less developed societies are socially stabilized and integrated and the people can realistically assess their actual resource and ecological position. Then, she feels, the people will make reasonable family-size choices in accordance with that position.

The Demographic Transition

A great many social and economic factors have been associated in the past with declining fertility in various societies. Among them are the general level of education, the availability and quality of health care, the degree of urbanization, the social and economic status of women and the opportunities open to them for education and employment outside the home, the provision of social security for old age, and the costs to families of raising and educating each child. The more extensive each of these factors is, the lower fertility generally will be. In addition, later marriage, lower tolerance for illegitimacy, low infant mortality, and extended breast-feeding all operate directly to reduce fertility. In most LDCs, levels of health care, education, and women's status remain low for the poor majority, while marriage comes early and infant mortality rates are high.

Most family planning programs in the 1960s made little effort to influence any of these factors, as demographer Kingsley Davis pointed out in 1967. [84] Those that tried to influence people at all confined themselves to emphasizing the economic and health advantages of small families to parents and their children.

In the 1950s and 1960s, government officials, economic advisors, and many demographers believed that the process of economic development would automatically bring about the higher levels of education and urbanization in LDCs that have elsewhere been associated with declines in fertility, and thus would cause a "demographic transition" in LDCs. These people favored family planning because they thought it would facilitate the supposedly inevitable demographic transition, although they believed that no significant reduction in fertility could occur until the prerequisite (but unknown) degree of development had been reached.

Numerous studies have established quite clearly that population growth is *in itself* a major barrier to economic development. Economist Goran Ohlin wrote in 1967:

The simple and incontestable case against rapid population growth in poor countries is that it absorbs very large amounts of resources which may otherwise be used both for increased consumption and above all, for development . . . The stress and strain caused by rapid demographic growth in the developing world is actually so tangible that there are few, and least of all planners and economists of the countries, who doubt that per capita incomes would be increased faster if fertility and growth rates were lower . . . . [85]

[83] Ibid.
[84] *Population policy: will current programs succeed?* See also Davis, *Zero population growth: The Goal and the Means*.
[85] *Population control and economic development*, p. 53.

The potential value of population control in aid programs to LDCs has also been studied intensively. The late economist Stephen Enke did much of the analysis, and his conclusions may be summarized in three points: (1) channeling economic resources into population control rather than into increasing production "could be 100 or so times more effective in raising per capita incomes in many LDCs"; (2) an effective birth control program might cost only 30 cents per capita per year, about 3 percent of current development programs; and (3) the use of bonuses to promote population control is "obvious in countries where the 'worth' of permanently preventing a birth is roughly twice the income per head." [86]

Enke's results were strongly supported by computer simulation work by systems analyst Douglas Daetz, who examined the effects of various kinds of aid in a labor-limited, nonmechanized agricultural society. [87] His results brought into sharp question the desirability of aid programs not coupled with population control programs. They might provide temporary increases in the standard of living, but these would soon be eaten up by population expansion. In many circumstances, population growth and aid inputs may interact to cause the standard of living to *decline below* the pre-aid level.

As a result of studies like Ohlin's, Enke's, and Daetz', family planning began to be incorporated into assistance programs for LDCs in the 1960s. But the purpose in most cases was only to reduce growth rates to more "manageable" levels by eliminating "unwanted births." This great faith of economists and demographers in the potential of industrial development to bring about a spontaneous demographic transition, which, aided by family planning, would reduce population growth and accelerate the development process, encouraged LDC governments to relax under the illusion that *all* their social and economic problems were being solved. Unfortunately, their faith was misplaced.

Reliance on a demographic transition was misplaced for many reasons, not the least of which is uncertainty as to exactly what caused the original one in nineteenthcentury Europe. [88] And, as was pointed out in Chapter 5, conditions in contemporary LDCs in many ways are markedly different from those in Europe and North America one to two centuries ago when fertility began to decline there.

By the mid- 1960s, although several LDCs had apparently reached quite advanced degrees of industrial development, there was little sign of a general decline in fertility. Birth rates dropped in some countries, but they remained high, or in a few cases even rose, in other, supposedly eligible countries. Because of this unexpected result, there has been some argument among demographers whether the theory of the demographic transition can even be applied to LDCs and whether there is good reason to hope that it will occur in most of them.

An analysis of fertility trends in some Latin American countries (often cited as prime examples of nonconformity to demographic transition theory) by demographer Stephen Beaver indicates that a demographic transition has begun or is at least incipient in the countries he examined. [89] But, he suggests, cultural and economic factors can cause time lags in the process. A considerably broader spectrum of factors may influence fertility than just reduced mortality (especially of infants), increasing urbanization, and industrialization, which are classically believed to be the primary causes of declining fertility.

It is becoming increasingly clear that industrialization -- the style of development undertaken by most developing countries -- is not conducive to a demographic transition. This seems to be so because industry in most LDCs employs and benefits only a fraction of the population, creating a two-tiered society in which the majority are left untouched by modernization. [90] Such unequal distribution of the benefits of modernization (access to adequate food, clothing, decent shelter, education, full-time employment, medical and health care, etc.) is most pronounced in rural areas, where some 70 percent of the population of LDCs live.

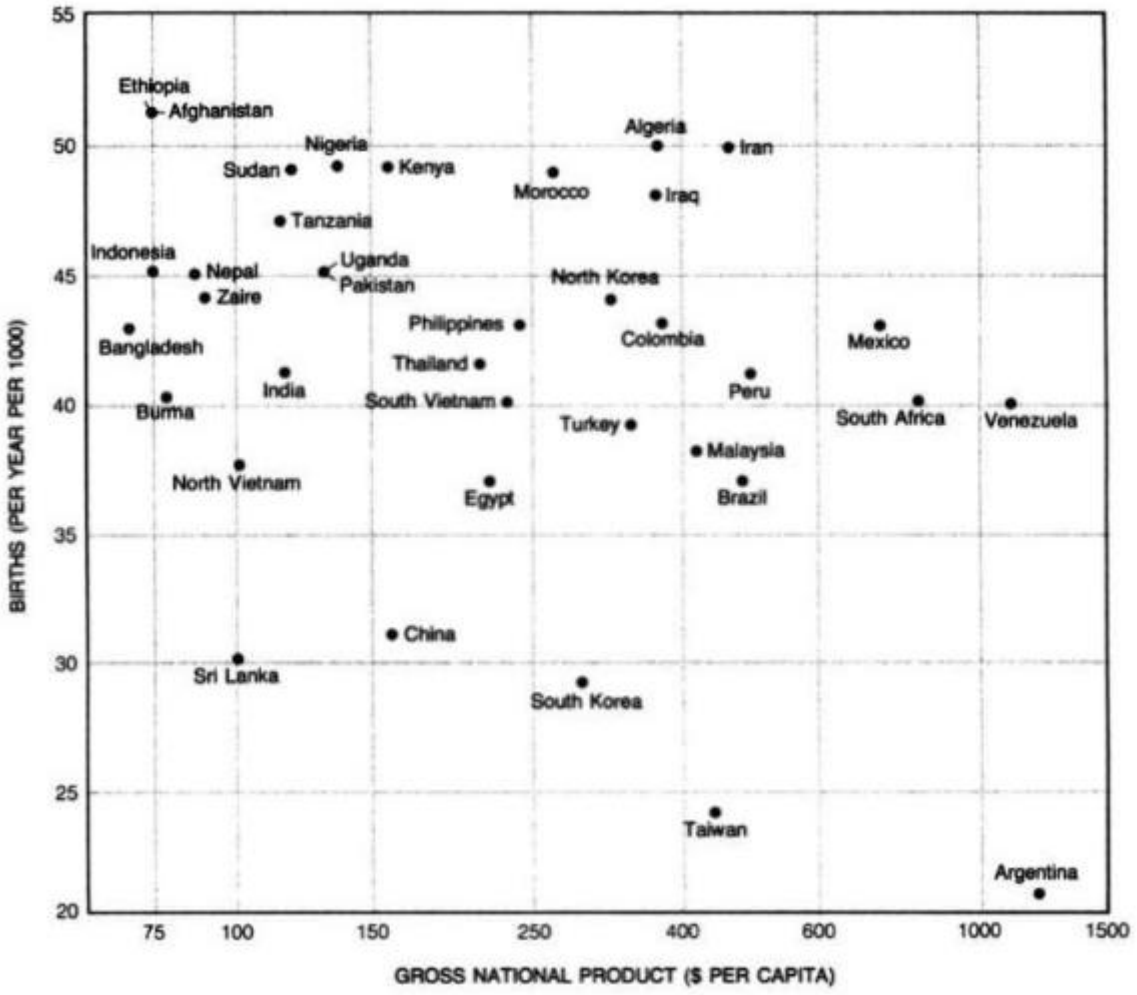

FIGURE 13-5
There is an absence of any clear relation between the birth rate and the level of development (as measured by per-capital GNP) in the less developed countries with more than 10 million population. A decline in birth rates has occurred recently in a number of these nations. (From Demeny, 1974.)

Per capita Gross National Product is a statistic often used to measure the extent of "development" that has taken place in a given country; per-capita GNP, however, is an averaged figure that may conceal very large differences among income groups. And the correlation of degrees of development as measured by per-capita GNP with reduction in fertility is extremely mixed, to say the least (Figure 13-5). One explanation is that, in strongly two-tiered societies, birth control may be adopted by the affluent, educated minority, but not by the majority still living in poverty. The conclusion from this is that fertility will decline significantly only when the benefits of modernization are extended to all economic levels.

Economist Alan Sweezy has pointed out that, while this explanation may account for fertility declines in some instances, the expected declines have not occurred in some countries -- notably in Latin America -- even among the affluent and middle classes. [90a] He suggests that lingering strong traditions, including pro-natalist attitudes, may be a reason. In Latin America such

traditions are supported by the Roman Catholic Church, which still officially opposes "artificial" methods of birth control and abortion.

If a demographic transition should take place in

[90a] Economic development and fertility change.

LDCs, a decline from present high fertility to replacement level alone would require considerable time, probably at least a generation. And time is running very short. If appropriate kinds of development and vigorous family planning programs had been initiated just after World War II, when death control and the ideas of economic assistance were first introduced in LDCs, the population problem might be of more manageable dimensions today. But plainly it would still be with us. Without such a history, even if the strongest feasible population control measures were everywhere in force today, the time lag before runaway population growth could be appreciably slowed, let alone arrested, would still be discouragingly long. For most LDCs it will be *at least* four generations before their populations cease to expand -- unless catastrophe intervenes -- because of the age composition of their populations. Even if replacement reproduction were attained by 2005, most LDC populations would at least double their 1970 populations, and some would increase *3.5-fold*. [91]

This built-in momentum virtually guarantees that, for many less developed countries, shortage of resources and the environmental and social effects of overpopulation will combine to prevent sufficient "development" to induce a demographic transition. Complacently counting on either a spontaneous demographic transition or on voluntary family planning programs -- or even a combination -- to reduce population growth and thereby ensure successful development would therefore be a serious mistake. The establishment of family planning programs may make it easier to improve social conditions in poor countries, but it is no substitute for appropriate development; and it is also clear that development alone cannot lead to a reduction of population growth on the needed scale.

POPULATION CONTROL: DIRECT MEASURES

Before any really effective population control can be established, the political leaders, economists, national planners, and others who determine such policies must be convinced of its necessity. Most governments have been reluctant to try measures beyond traditional family planning that might be effective because they considered them too strong, too restrictive, and too much against traditional attitudes. They are also, reasonably enough, concerned about resistance from political opponents or the populace at large. In many countries such measures may never be considered until massive famines, political unrest, or ecological disasters make their initiation imperative. In such emergencies, whatever measures are economically and technologically expedient will be likeliest to be imposed, regardless of their political or social acceptability. A case in point was the sudden imposition in 1976 of compulsory sterilization in some Indian states and for government employees in Delhi, following two decades of discouraging results from voluntary family planning.

People should long ago have begun exploring, developing, and discussing all possible means of population control. But they did not, and time has nearly run out. Policies that may seem totally unacceptable today to the majority of people at large or to their national leaders may be seen as very much the lesser of evils only a few years from now. The decade 1965-1975 witnessed a virtual revolution in attitudes toward curbing population growth among LDC leaders, if not necessarily among their people. Even family planning, easily justified on health and welfare grounds alone and economically feasible for even the poorest of countries, was widely considered totally unacceptable as a government policy as recently as 1960.

Among objections to population control measures cited by demographer Bernard Berelson in 1969 were the need for improved contraceptive technology; lack of funds and trained personnel to carry out all proposed programs; doubt about effectiveness of some measures, leading to failure to implement them; and moral objections to some proposals such as abortion, sterilization, various social measures, and especially to any kind of compulsion. [92]

Most objections to population control policies, how-

---

[91] Thomas Frejka, *The future of population growth: alternative paths to equilibrium*.

[92] See Berelson's *Beyond family planning, for a conservative view of potential measures for population control*. Since 1969, Berelson has found many formerly unacceptable measures to have become much more acceptable: for instance, An evaluation of the effects of population control programs; and Freedman and Berelson, *The record of family planning programs*, published in 1974 and 1975 respectively.

ever, can be overcome or are likely to disappear with time and changing conditions; indeed many of them already have. Contraceptive technology has been improved in recent years (see Appendix 4). Promising methods of birth control that are not now technologically possible should also be developed, so that they can be made available. [92a] Further generous assistance from developed countries could remove remaining economic and lack of personnel barriers to population-control programs in LDCs. The effectiveness of a measure can only be evaluated after it has been tried. Moral acceptability is very likely to change as social and economic conditions change in most societies, as demonstrated by the reversal of abortion policies in many countries between 1967 and 1975.

The struggle for economic development in the LDCs is producing considerable social upheaval, which will particularly affect such basic elements of society as family structure. Radical changes in family structure and relationships are inevitable, whether population control is instituted or not. Inaction, attended by a steady deterioration in living conditions for the poor majority, will bring changes everywhere that no one could consider beneficial. Thus, it is beside the point to object to population-control measures simply on the grounds that they might change the social structure or family relationships.

Among proposed general approaches to population control are family planning, the use of socioeconomic pressures, and compulsory fertility control. Maximum freedom of choice is

provided by traditional family planning; but family planning alone should not be regarded as "population control" when it includes no consideration of optimum population size for the society and makes no attempt to influence parental goals.

The use of abortion and voluntary sterilization to supplement other forms of birth control can quite properly be included as part of family planning and made available at costs everyone can afford. This, of course, has been done in a few countries with considerable apparent success (Table 13-4). Moreover, there is still a good deal of room for expansion of family planning services in LDCs, where they are not yet available to more than a fraction of most populations. Family planning programs not only provide the means of contraception, but, through their activities and educational campaigns, they spread the idea of birth control among the people. *These programs should be expanded and supported throughout the world as rapidly and as fully as possible, but other measures should be instituted immediately as well*. Given the family size aspirations of people everywhere, additional measures beyond family planning will unquestionably be required in order to halt the population explosion -- quite possibly in many DCs as well as LDCs.

Socioeconomic Measures

Population control through the use of socioeconomic pressures to encourage or discourage reproduction is the approach advocated by, among others, demographer Kingsley Davis, who originated many of the following suggestions. [93] The objective of this approach would be to influence the attitudes and motivations of individual couples. An important aspect would be a large-scale educational program through schools and communications media to persuade people of the advantages of small families to themselves and to their society. Information on birth control, of course, must accompany such educational efforts. This is one of the first measures that can be adopted, and it has been increasingly employed in many of the more active family planning programs in LDCs. It has also been used in some DCs, notably the U.S. and England, mainly, but not entirely, by private groups such as Planned Parenthood and ZPG.

As United States taxpayers know, income tax laws have long implicitly encouraged marriage and childbearing, although recent changes have reduced the effect somewhat. Such a pronatalist bias of course is no longer appropriate. In countries that are affluent enough for the majority of citizens to pay taxes, tax laws could be adjusted to favor (instead of penalize) single people,

[92a] Unfortunately, this area is still being seriously neglected. It has been estimated that funds could fruitfully be tripled over 1974 levels to take advantage of existing knowledge and trained personnel in research on reproduction and development of new contraceptives. (M. A. Koblinsky, F. S. Jaffe, and R. O. Greep, *Funding for reproductive research: The status and the needs*.) See also Barbara J. Culliton, "Birth control: Report argues new leads are neglected" (*Science*, vol. 194, pp. 921-922, November 26, 1976) for a discussion of a forthcoming Ford Foundation Report, Reproduction and human welfare.

[93] Davis, *Population policy*.

working wives, and small families. Other tax measures might also include high marriage fees, taxes on luxury baby goods and toys, and removal of family allowances where they exist.

Other possibilities include the limitation of maternal or educational benefits to two children per family. These proposals, however, have the potential disadvantage of heavily penalizing children (and in the long run society as well). The same criticism may be made of some other tax plans, unless they can be carefully adjusted to avoid denying at least minimum care for poor families, regardless of the number of children they may have.

A somewhat different approach might be to provide incentives for late marriage and childlessness, such as paying bonuses to first-time brides who are over 25, to couples after five childless years, or to men who accept vasectomies after their wives have had a given number of children. [94] Lotteries open only to childless adults have also been proposed. The savings in environmental deterioration, education, and other costs would probably justify the expenditure. All of these measures, of course, suffer the drawback of influencing the poor to a greater degree than the rich. That would be unfortunate, since the addition of a child to an affluent family (which has a disproportionate impact on resources and environment) is in many ways more harmful to society than the addition of a child to a poor family.

Adoption to supplement small families for couples who especially enjoy children can be encouraged through subsidies and simplified procedures. It can also be a way to satisfy couples who have a definite desire for a son or daughter; further research on sex determination should be pursued for the same reason. A special kind of social-security pension or bond could be provided for aging adults who have few or no children to support them in their old age.

The latter idea, proposed in detail by economist Ronald Ridker, has been tried with some success on tea estates in southern India. [95] As implemented, the plan made monthly deposits in a pension fund for each female worker enrolled in the plan as long as she spaced her children at least three years apart and had no more than three. If more children were born, the payments were reduced. Since managers of the tea estates were already paying maternity and health benefits, the costs of the pension fund were at least partially offset by savings from those. A large majority of the women signed up for the program, and within the first four years there were substantial drops not only in fertility, but in infant mortality and in worker absenteeism. [96] The first pilot project included only about 700 women; it remains to be seen whether implementation of the pension plan on other tea estates and in other situations in India will be equally successful.

There are many possibilities in the sphere of family structure, sexual mores, and the status of women that can be explored. [97] With some exceptions, women have traditionally been allowed to fulfill only the roles of wife and mother. Although this has changed in most DCs in recent decades, it is still the prevailing situation in most LDCs, particularly among the poor and uneducated. Anything that can be done to diminish the emphasis upon these traditional roles and provide women with equal opportunities in education, employment, and other areas is likely to reduce the birth rate. Measures that postpone marriage and then delay the first child's birth also help to encourage a reduction in birth rates. The later that marriage and the first child occur, the more time the woman will have to develop other interests. One of the most important potential

measures for delaying marriage, and directly influencing childbearing goals as well, is educating and providing employment for women.

Women can be encouraged to develop interests outside the family other than employment, and social life could be centered around these outside interests or the couple's work, rather than exclusively within the neighborhood and family. Adequate care for pre-school children should be provided at low cost (which, moreover, could provide an important new source of employment). Provision of child care seems more likely to encourage employment outside the home, with concomitant low reproduction, than to encourage reproduction. Women represent a

---

[94] A study has been made of the economic feasibility of such a policy for the United States by Larry D. Barnett (*Population policy: payments for fertility limitation in the U.S.*).

[97] Judith Blake, *Demographic science and the redirection of population policy*; Reproductive motivation; Alice Taylor Day, *Population control and personal freedom: are they compatible?*

large, relatively untapped pool of intellectual and technical talent; tapping that pool effectively could help reduce population growth and also would provide many other direct benefits to any society.

Social pressures on both men and women to marry and have children must be removed. As former Secretary of Interior Stewart Udall observed, "All lives are not enhanced by marital union; parenthood is not necessarily a fulfillment for every married couple." [98] If society were convinced of the need for low birth rates, no doubt the stigma that has customarily been assigned to bachelors, spinsters, and childless couples would soon disappear. But alternative lifestyles should be open to single people, and perhaps the institution of an informal, easily dissolved "marriage" for the childless is one possibility. Indeed, many DC societies now seem to be evolving in this direction as women's liberation gains momentum. [99] It is possible that fully developed societies may produce such arrangements naturally, and their association with lower fertility is becoming increasingly clear. In LDCs a childless or single lifestyle might be encouraged deliberately as the status of women approaches parity with that of men.

Although free and easy association of the sexes might be tolerated in such a society, responsible parenthood ought to be encouraged and illegitimate childbearing could be strongly discouraged. One way to carry out this disapproval might be to insist that all illegitimate babies be put up for adoption -- especially those born to minors, who generally are not capable of caring properly for a child alone. [100] If a single mother really wished to keep her baby, she might be obliged to go through adoption proceedings and demonstrate her ability to support and care for it. Adoption proceedings probably should remain more difficult for single people than for married couples, in recognition of the relative difficulty of raising children alone. It would even be possible to

require pregnant single women to marry or have abortions, perhaps as an alternative to placement for adoption, depending on the society.

Somewhat more repressive measures for discouraging large families have also been proposed, such as assigning public housing without regard for family size and removing dependency allowances from student grants or military pay. Some of these have been implemented in crowded Singapore, whose population program has been counted as one of the most successful.

All socioeconomic measures are derived from knowledge of social conditions that have been associated with low birth rates in the past. The more repressive suggestions are based on observations that people have voluntarily controlled their reproduction most stringently during periods of great social and economic stress and insecurity, such as the Depression of the 1930s. [101] In a sense, all such proposals are shots in the dark. Not enough is known about fertility motivation to predict the effectiveness of such policies. Studies by demographer Judith Blake [102] and by economist Alan Sweezy [103] for instance, have cast serious doubt on the belief that economic considerations are of the greatest importance in determining fertility trends. Sweezy has shown that the decline of fertility in the 1930s in the United States was merely a continuation of an earlier trend. If their views are correct, then severely repressive economic measures might prove to be both ineffective and unnecessary as a vehicle for population control, as well as socially undesirable. At the very least, they should be considered only if milder measures fail completely.

Involuntary Fertility Control

The third approach to population limitation is that of involuntary fertility control. Several coercive proposals deserve discussion, mainly because some countries may ultimately have to resort to them unless current trends in birth rates are rapidly reversed by other means. [104] Some

[100] The tragedy of teenage single mothers in the U.S. is described by Leslie Aldridge Westoff in *Kids with kids*. The adverse health and social effects of teenage child-bearing in an affluent society have recently been documented by several studies. One good sample can be found in a special issue of *Family planning perspectives*, Teenagers, USA.

involuntary measures could be less repressive or discriminatory, in fact, than some of the socioeconomic measures suggested.

In the 1960s it was proposed to vasectomize all fathers of three or more children in India. The proposal was defeated then not only on moral grounds but on practical ones as well; there simply were not enough medical personnel available even to start on the eligible candidates, let alone to deal with the new recruits added each day! Massive assistance from the developed world in the form of medical and paramedical personnel and/or a training program for local people nevertheless might have put the policy within the realm of possibility. India in the mid-1970s not only entertained the idea of compulsory sterilization, but moved toward implementing it, perhaps fearing that famine, war, or disease might otherwise take the problem out of its hands. This decision was greeted with dismay abroad, but Indira Gandhi's government felt it had little other choice. There is too little time left to experiment further with educational programs and hope that social change will generate a spontaneous fertility decline, and most of the Indian population is too poor for direct economic pressures (especially penalties) to be effective.

A program of sterilizing women after their second or third child, despite the relatively greater difficulty of the operation than vasectomy, might be easier to implement than trying to sterilize men. This of course would be feasible only in countries where the majority of births are medically assisted. Unfortunately, such a program therefore is not practical for most less developed countries (although in China mothers of three children are commonly "expected" to undergo sterilization).

The development of a long-term sterilizing capsule that could be implanted under the skin and removed when pregnancy is desired opens additional possibilities for coercive fertility control. The capsule could be implanted at puberty and might be removable, with official permission, for a limited number of births. No capsule that would last that long (30 years or more) has yet been developed, but it is technically within the realm of possibility.

Various approaches to administering such a system have been offered, including one by economist Kenneth Boulding. [105] His proposal was to issue to each woman at maturity a marketable license that would entitle her to a given number of children -- say, 2.2 in order to have an NRR = 1. Under such a system the number could be two if the society desired to reduce the population size slowly. To maintain a steady size, some couples might be allowed to have a third child if they purchased "decichild" units from the government or from other women who had decided not to have their full allotments of children or who found they had a greater need for the money. Others have elaborated on Boulding's idea, discussing possible ways of regulating the license scheme and alternative ways of alloting the third children. [106] One such idea is that permission to have a third child might be granted to a limited number of couples by lottery. This system would allow governments to regulate more or less exactly the number of births over a given period of time.

Social scientist David Heer has compared the social effects of marketable license schemes with some of the more repressive economic incentives that have been proposed and with straightforward quota systems. [107] His conclusions are shown in Table 13-5.

Of course, a government might require only implantation of the contraceptive capsule, leaving its removal to the individual's discretion but requiring reimplantation after childbirth. Since having a child would require positive action (removal of the capsule), many more births would be

prevented than in the reverse situation. Certainly unwanted births and the problem of abortion would both be entirely avoided. The disadvantages (apart from the obvious moral objections) include the questionable desirability of keeping the entire female population on a continuous steroid dosage with the contingent health risks, and the logistics of implanting capsules in 50 percent of the population between the ages of 15 and 50.

Adding a sterilant to drinking water or staple foods is a suggestion that seems to horrify people more than most proposals for involuntary fertility control. Indeed, this

would pose some very difficult political, legal, and social questions, to say nothing of the technical problems. No such sterilant exists today, nor does one appear to be under development. To be acceptable, such a substance would have to meet some rather stiff requirements: it must be uniformly effective, despite widely varying doses received by individuals, and despite varying degrees of fertility and sensitivity among individuals; it must be free of dangerous or unpleasant side effects; and it must have no effect on members of the oposite sex, children, old people, pets, or livestock.

Physiologist Melvin Ketchel, of the Tufts University School of Medicine, suggested that a sterilant could be developed that would have a very specific action -- for example, preventing implantation of the fertilized ovum. [108] He proposed that it be used to reduce fertility levels by adjustable amounts, anywhere from 5 to 75 percent, rather than to sterilize the whole population completely. In this way, fertility could be adjusted from time to time to meet a society's changing needs, and there would be no need to provide an antidote. Contraceptives would still be needed for couples who were highly motivated to have small families. Subfertile and functionally sterile couples who strongly desired children would be medically assisted, as they are now, or encouraged to adopt. Again, there is no sign of such an agent on the horizon. And the risk of serious, unforeseen side effects would, in our opinion, militate against the use of any such agent, even though this plan has the advantage of avoiding the need for socioeconomic pressures that might tend to discriminate against particular groups or penalize children.

Most of the population control measures beyond family planning discussed above have never been tried. Some are as yet technically impossible and others are and probably will remain unacceptable to most societies (although, of course, the *potential* effectiveness of those least acceptable measures may be great).

Compulsory control of family size is an unpalatable idea, but the alternatives may be much more horrifying. As those alternatives become clearer to an increasing number of people in the 1980s, they may begin *demanding* such control. A far better choice, in our view, is to expand the use of milder methods of influencing family size preferences, while redoubling efforts to ensure that the means of birth control, including abortion and

[108] *Fertility control agents as a possible solution to the world population problem*, pp. 687-703.

sterilization, are accessible to every human being on Earth within the shortest possible time. If effective action is taken promptly against population growth, perhaps the need for the more extreme involuntary or repressive measures can be averted in most countries.

POPULATION CONTROL AND DEVELOPMENT

Population control cannot be achieved in a social or economic vacuum, of course. To formulate effective population control measures, much greater understanding is needed about all peoples' attitudes toward reproduction, and how these attitudes are affected by various living conditions, including some that seem virtually intolerable to people in developed countries. Even more, it is essential to know what influences and conditions will lead to changes in attitudes in favor of smaller families.

The economists and demographers who believed that urbanization and industrialization of LDCs would automatically induce a demographic transition in those societies seem to have been disastrously wrong. While they waited for the birth rate to fall, one billion people were added to the human population. At the very least, it is obvious that the causes of demographic transitions are far more complex than was once believed. But the social scientists may have been wrong mainly in their approach. Many aspects of modernization may indeed have important influences on reproductive behavior.

Such influences, of course, fall outside the purview of population programs; they are an integral part of development as it affects -- or fails to affect -- each member of a society. When development is the kind that improves the living conditions of everyone down to the poorest farm worker, development that starts *at the grass roots level*, then there is hope that poverty, hunger, disease, and hopelessness might be reduced -- and along with them the desire for many children. [109]

The general problems of LDC development are discussed in detail in Chapter 15, but its indirect effects on fertility are worth mentioning here. While no one factor of development can be singled out as ever having "triggered" a decline in fertility -- no particular level of infant mortality or per-capita GNP, for instance -- a *constellation of factors* does often seem to be associated with such declines. Among these are rural development and land reform favoring small, family-owned farms; availability of adequate food, basic health care, and education (especially of women) to the entire population; industries favoring labor-intensive, rather than capitalintensive, means of

production; and a relatively small income gap between the richest and poorest segments of the population. [110]

Table 13-6 compares some of these interrelated factors in nine less developed nations, four of which have shown significant drops in fertility since 1960 and five of which have not. While each of the nine countries, like nearly all LDCs, exhibits some of the salient factors listed above, those with substantially reduced fertility much more commonly manifest them. Understanding of the important influences on reproductive behavior and how they operate is so far sketchy at best. Achieving a solid base for population policy may be one of the most important -and perhaps most difficult -- research assignments for the next decade.

Since the goals of both development and population control are supposedly identical -- an improvement in the well-being of all human beings in this and future generations -- it seems only reasonable to plan each to reinforce the other. Emphasis accordingly should be placed on policies that would further the goals of both family limitation and development -- for example, rural development and land tenure reform; increased agricultural output; universal primary education for children; old-age support schemes; and improved health care and nutrition, especially for mothers and children.

Survival of human society nevertheless seems likely to require the imposition of direct population control measures beyond family planning in most LDCs. There is no guarantee that processes of modernization can quickly enough induce the necessary changes in attitudes that might bring growth to a halt. High priority should be given to stimulating those attitude changes and counteracting the effects of pronatalist traditions.

Howe, et al., *The U.S. and world development; agenda for action 1975*, Praeger, New York, 1975; *1975 and 1976 World population data sheets,* Population Reference Bureau, Inc Washington, D.C.; *World population estimates, 1975*, The Environmental Fund, Inc., Washington, D.C.; Nortman, "Population and family planning programs", *Reports on population and family planning*, Population Council, no. 2, 6th ed., Dec 1974; *World Bank Atlas, 1975*, December, Washington, D.C.

But while some people seek the best means of achieving population control, in other quarters the debate continues as to whether it is necessary -- or even desirable.

Population Politics

I am not sure that the dictatorship of the proletariat, especially if led by an elite, will solve the problem of social justice; I am certain starvation will not solve the problem of overpopulation.

--Tom O'Brien,

Marrying Malthus and Marx

Family planning programs have spread throughout the less developed world and are now established in the majority of less developed countries. Many countries, especially those with long-established programs that have been frustrated by lack of success in reducing birth rates simply through making means of birth control available, have progressed to measures beyond family planning. As could be expected, this has aroused opposition, informed and uninformed, from many quarters. Some groups see threats to their personal liberties; even more commonly, people see threats to their economic or political interests. In addition, there are many proponents of population control who strongly disagree on the most appropriate approach. [111] By 1974, when the United Nations World Population Conference took place in Bucharest, the chorus of clashing viewpoints was almost deafening. [112] Most press reports and coverage of the Conference by

special groups conveyed an impression of enormous confusion and prevailing disagreement, [113] despite the ultimate ratification of a World Population Plan of Action and 21 resolutions. [114]

A very useful summary of all the various views of the population problem and how (or whether) to deal with it has been compiled by demographer Michael S. Teitelbaum. [115] Because it is the best listing we have seen, we are borrowing Teitelbaum's outline for the framework of the following discussion. [116]

Positions Against Special Population Programs and Policies

Pronatalist. This viewpoint favors rapid population growth to boost economic growth and an expanding labor supply, as well as to increase opportunities for economies of scale in small countries. Pronatalists believe there is strength in numbers (both political and military) and are more concerned about competition with rapidly growing neighboring countries or among segments of their own populations than about the disadvantages of rapid growth. This group now seems to be a diminishing minority.

Revolutionist. Revolutionaries oppose population programs because they may alleviate the social and political injustices that might otherwise lead to the revolution they seek. This view is particularly common in Latin America. [117] (Conversely, many politicians support family planning in the hope that it will dampen the revolutionary fires.)

Anti-colonial and genocide positions. This group is very suspicious of the motives of Western population control advocates. Some believe that effective population programs would retard development and maintain LDCs in economic subservience to DCs. Others see population

[111] National Academy of Sciences, *In search of population policy*.

[112] J. Mayone Stycos, *Demographic chic at the UN*.

[113] The list of accounts is very long, even leaving out a plethora of anticipatory books and articles. Here is a partial one: Anthony Astrachan, *People are the most precious*; Donald Gould, *Population polarized*; P. T. Piotrow , *World plan of action and health strategy approved at population conferences*; Conrad Taeuber, *Policies on population around the world*; Brian Johnson, *The recycling of Count Malthus*; M. Carder and B. Park, *Bombast in Bucharest*; D. B. Brooks and L. Douglas, *Population, resources, environment: the view from the UN*; W. P. Mauldin, et al., *A report on Bucharest*; Marcus P. Franda, *Reactions to America at Bucharest*; *Concerned Demography*, "Emerging population alternatives"; International Planned Parenthood Federation, (IPPF) *People*, special issue, vol. 1, no. 3, 1974; in addition, IPPF published a daily newspaper called *Planet* during the conference.

[114] United Nations, *Report of the UN World Population Conference, 1974*.

[115] Population and development: is a consensus possible?

[116] Bernard Berelson has also described the conflicting views on population in the *Population Council Annual Report* 1973, pp. 19-27, and The great debate on population policy. The latter was written as a dialog among three "voices," representing the family planning advocates, those who see "development" as the important issue, and academic critics of the family planning approach to population control. The dialog is informative, often witty, but

unfortunately leaves the reader with an impression of much greater consensus than probably exists among the viewpoints.

[117]J. Mayone Stycos, *Family planning: reform and revolution*.

programs as an effort by DCs to "buy development cheaply." The most extreme position is taken by those who regard population control as a racist or genocidal plot against nonwhite citizens of LDCs. Holders of this position blame resource shortage and environmental problems exclusively on the greediness of rich countries. To the extent that high fertility in LDCs is a problem, they emphasize that it is due to their poverty, which in turn is caused by overconsumption in DCs. [118]

Accommodationist. This viewpoint is basically anti-Malthusian: because history shows that Earth is capable of supporting far more people than Malthus thought, he was wrong; these people believe that further improvements in agriculture and technology will permit accommodation of a much larger population than today's. To them what is called overpopulation is really underemployment; restructuring the economic system will allow societies to provide jobs and meet the basic needs of everyone, no matter how many. The slogan adopted by the New Internationalist for the Population Conference -- "Look after the people and population will look after itself" -- epitomizes this position. [119]

The problem-is-population-distribution. Some people holding this view simplistically compare population densities of different regions without regard to available resources and means of support. They also focus on the serious problem of urban migration in LDCs and conclude that policies should concentrate on population redistribution rather than on birth control. [120]

Mortality and social security. This view concentrates on the significance of infant and child mortality in motivating reproductive behavior; if infant mortality were reduced, fertility would automatically decline. This view is also held in varying degrees by many propopulation control advocates as well as those against it. Barry Commoner [121] subscribes to it, but he quotes a formula devised by AID. Whether the relationship is as clear as is commonly believed has been called into question by Alan Sweezy, among others. [122]

The other side of this coin is social security -- the need for children, especially sons, to support parents in old age. [123]

Status and roles of women. Social pressures defining the role of women as wives and mothers, with status attached primarily to that role, are a major cause of high fertility, according to this view. Large families are likely to prevail until alternative roles are made available to all women. [124]

The religious doctrinal position. There are two distinct, but not necessarily mutually exclusive views here. One is essentially fatalistic: "Be fruitful and multiply, God will provide." This view is common among both Western and Eastern religions. The other (mainly the Roman Catholic Church) sees population growth as a problem, but regards most forms of birth control as more or less immoral. [125]

Medical risk. People holding this view are more impressed by the risks that attend the use of contraceptives such as the pill and the IUD, and surgical procedures such as abortion and sterilization than by the risks run by not using them. (The risk of death from childbearing alone is considerably higher, especially among the poor in LDCs, than any of these, and both maternal and infant mortality are known to be reduced substantially by the use of birth control for birth spacing.) [126] A milder version of this view is held by large segments of the medical profession who oppose the distribution of the pill without prescription and the insertion of IUDs by paramedical personnel, despite the established safety of both procedures compared to the consequences of not using them. [127]

---

[118]This perspective has been put forth by Barry Commoner, *How poverty breeds overpopulation (and not the other way around)*; and Pierre Pradervand , *The Malthusian man*. Pradervand and Commoner, among others, also oppose present population programs on anticolonialist grounds.

[119]Peter Adamson, *A population policy and a development policy are one and the same thing*.

[120]Maaza Bekele, *False prophets of doom*. This article expresses this and the above three viewpoints clearly.

[121]Commoner, *How poverty breeds overpopulation*.

[122]Recent light.

[123]Mamdani, *Myth of population control*

[124]Blake, *Reproductive motivation*; Day, *Population control and personal freedom*; Ceres, *Women: a long-silent majority*.

[125]Pope Paul VI, *Humanae Vitae*.

[126]A. Omran, *Health benefits*; Buchanan, *Effects of childbearing*; Eckholm and Newland, *Health*.

[127]Mauldin, *Family planning programs and fertility declines*.

Holistic development. Holders of this view are "demographic transition" believers who are convinced that social and economic development are responsible for whatever declines in fertility have occurred in LDCs, not family planning programs, which they consider a waste of effort and funds that should be put into development. [128] **Social justice.** This position emphasizes redistribution of wealth within and among nations to improve the condition of the poor. [129] It is related to the idea of grassroots development, but is somewhat more extreme in that many of its proponents feel that redistribution of wealth is the *only* policy that will reduce population growth and solve other problems as well.

Positions Supporting the Need for Population Programs and Policies

Population hawks. Teitelbaum sums up this position as follows:

> . . . Unrestrained population growth is the principal cause of poverty, malnutrition, and environmental disruption, and other social problems. Indeed we are faced with impending catastrophe on food and environmental fronts. [130]
>
> . . . Such a desperate situation necessitates draconian action to restrain population growth, even if coercion is required. "Mutual coercion, mutually agreed upon." [131]
>
> . . . Population programs are fine as far as they go, but they are wholly insufficient in scope and strength to meet the desperate situation. [132]

Provision of services. This viewpoint holds that family planning programs are essential for reducing birth rates and that there is still a great unmet demand for birth control in LDCs; what is needed is to expand family planning services to meet the demand. [133] Part of the failure of family planning is due to provision of inadequate contraceptive technologies. [134] This position is held most strongly by administrators and associates of family planning programs and their donor agencies.

Human rights. This position, held by virtually everyone who is in favor of family planning or other population control policies, derives from the idea that there is a fundamental human right for each person responsibly to determine the size of his or her family. [135]

Another right that has been recognized in many countries including the United States [136] is that of women to control their bodies. This is especially relevant to the issue of abortion, but applies also to contraception and sterilization. Family planning also contributes to health, especially of women and children; and one more human right is that to health care.

Population programs plus development. Here again we quote Teitelbaum, who expressed it well:

. . . Social and economic development are necessary but not sufficient to bring about a new equilibrium of population at low mortality and fertility levels. Special population programs are also required. [137]

---

[128] Bekele, *False prophets*; Commoner, *How poverty breeds overpopulation*. A more sophisticated form is Adamson's (A population policy)--at least he advocates development at the grass-roots level (see Social Justice section).

[129] Pradervand, *Malthusian man*; some writers for *Concerned Demography*.

[130] We, along with some colleagues, are considered among the principal proponents of this position (see especially P. Ehrlich, *The population bomb*, which is the most commonly cited source). Like most of the statements in this summary, this one is both exaggerated and oversimplified. We would not, for example, blame poverty or malnutrition principally on overpopulation, although it certainly contributes to their perpetuation. Likewise, population growth is one of three interacting causes of environmental deterioration; the others are misused technology and increasing affluence (see Chapter 12). As an aside, it is interesting that the first edition of the Population bomb, written almost a decade before this book, is still often cited both as if it reflected the situation in the mid-1970s and as if we still held precisely the same views today as we did then.

[131] Garrett Hardin, *The tragedy of the commons*.

[132] Davis, *Population policy*; P. R. Ehrlich and A. H. Ehrlich, *Population resources environment*, W. H. Freeman and Company, San Francisco, 1970 and 1972, chapter 10.

[133] Stycos, *Demographic chic*; Berelson, *Effects of Population Control Programs*.

[134] Mauldin, *Family planning programs and fertility declines*.

[135] UN Declaration on Population, Tehran, 1968, printed in Studies in *Family Planning*, no. 16, January 1967 and no. 26, January 1968. Teitelbaum omitted the important word "responsibly" in his discussion.

[136]Supreme Court decision on abortion, 1973.
[137]Advocates of this include Rich, *Smaller families*; James E. Kocher, *Rural development*; Grant, *Development*; and Lester R. Brown, *In the human interest*.

While we are usually classified by others as "population hawks," we agree more closely with this position in terms of what should be done. What follows, however, is far too mild a statement on the urgency of ending population growth; Teitelbaum discusses only the social aspects and completely leaves out environmental and resource constraints on population growth:

Too rapid population growth is a serious intensifier of other social and economic problems, and is one, though only one, of a number of factors behind lagging social and economic progress in many countries.

Some countries might benefit from larger populations, but would be better served by moderate rates of growth over a long period than by very rapid rates of growth over a shorter period.

An effective population program therefore is an essential component of any sensible development program.

This general position (including the portion just quoted) is widely held by social scientists, politicians, economists, and quite likely by Teitelbaum himself.Like the blind men with the elephant, each viewpoint grasps a piece of the truth, but none encompasses all of it. As should be evident, the above positions are by no means mutually exclusive, and probably none is held monolithically by anyone. Rather, most people argue from several related positions at once. Some apparently violent disagreements, when analyzed, turn out to be only a matter of emphasis or of leaving something out of the picture. Teitelbaum, Berelson, and others see the germ of a consensus emerging from the debate. If so, and if the consensus produces an effective approach to the population problem that all can more or less agree on, the controversy will have been worthwhile. But to the extent that population policies are connected to the larger confrontation between the rich developed world and the poor less developed world (with waters frequently muddied by China and the Soviet Union who say one thing about population control and practice another), consensus may prove to be elusive. Even more important, LDCs are unlikely to take very seriously population goals and policies recommended by DCs that do not impose such goals and policies upon their own people.

World Population Plan of Action

In view of the diversity of opinions held by various individuals and groups on population control, it is not surprising that the United Nations' *World Population Plan of Action* turned out to be a bulky, nearly unreadable document some 50 pages long. [138] Summing it up is almost impossible; the 20 resolutions and numerous recommendations covered virtually every subject that might affect or be affected by population growth. In the initial statement of "Principles and Objectives," the Plan declared:

The principal aim of social, economic and cultural development, of which population goals and policies are integral parts, is to improve levels of living and the quality of life of the people. Of all things in the world, people are the most precious. . . .

It then proceeded to affirm the rights of nations to formulate their own population policies, of couples and individuals to plan their families, and of women to participate fully in the development process. It condemned racial and ethnic discrimination, colonialism, foreign domination, and war. And it also expressed concern for preserving environmental quality, for maintaining supplies and distribution of resources, and for increasing food production to meet growing needs.More specifically with regard to population policies, the following recommendations were made: [139]

Governments should develop national policies on population growth and distribution, and should incorporate demographic factors into their development planning.
Developed countries should also develop policies on population, investment, and consumption with an eye to increasing international equity.
Nations should strive for low rather than high birth and death rates.
Reducing death rates should be a priority goal, aiming for an average life expectancy in all

[138]United Nations, *Report of the UN World Population Conference*, 1974.
[139]"Adapted from a summary by Piotrow, *World Plan of Action*.

countries of 62 by 1985 and 74 by 2000, and an infant mortality rate below 120 by 2000.
All nations should ensure the rights of parents "to determine in a free, informed and responsible manner the number and spacing of their children," and provide the information and means for doing so.
Family planning programs should be coordinated with health and other social services, and the poor in rural and urban areas should receive special attention.
Efforts should be made to reduce LDC birth rates from an average of 8 in 1974 to 30 per 1000 by 1985.
Nations are encouraged to set their own birth rate goals for 1985 and to implement policies to reach them.
Nations should make special efforts to tssist families as the basic social unit.
Equality of opportunity for women in education, employment and social and politicl spheres should be ensured.
Undesired migration, especially to cities, should be discouraged, principally by concentrating development in rural areas and small towns, but without restricting people's rights to move within their nation.
International agreements are needed to protect rights and welfare of migrant workers between countries and to decrease the "brain drain."
Demographic information should be collected, including censuses, in all countries.
More research is needed on the relation of population to various institutions and to social and economic trends and policies; on improving health; on better contraceptive technologies; on the relation of health, nutrition, and reproduction; and on ways to improve delivery of social services (including family planning).
Education programs in population should be strengthened.
Population assistance from international, governmental, and private agencies should be increased.
The Plan of Action should be coordinated with the UN's Second Development Decade strategy, reviewed every five years, and appropriately modified.

Unfortunately, a sense of urgency about reducing population growth, which had been present in the draft Plan, was lost in the final version under the pressure of political disagreement. The environmental and resource constraints on population growth were essentially left out of conference discussions and hence omitted from the Plan of Action. [140] Also, the value of family planning programs tended to be downgraded in favor of an overwhelming emphasis on "development" as the way to reduce birth rates.

The conference may not have blazed any radically new trails in its recommendations, but it still cannot be accused of taking a strictly narrow view of the population problem. Its neglect of environmental and resource aspects and the political problems that will accrue to those limitations is deplorable, but social and economic aspects were fully explored. Probably the conference's greatest value was to expose participants (many of whom did hold narrow views or were uninformed about some of the issues) to the information and viewpoints of others. And the mere existence of a world conference helped draw world attention to the population issue and emphasized that nations have a responsibility to manage their populations. Before the conference most national governments still seemed to believe that population problems were neither their concern nor within their ability to control.

The final Plan of Action was adopted by consensus of the 136 member nations (with reservations by the Vatican). Whether the resolutions and recommendations will be taken with the seriousness the problem warrants remains to be seen. For many countries it will not be easy, given the overwhelming problems their governments face. But on the answer hangs the future of humanity.

It was repeatedly emphasized at Bucharest that population control is no panacea for solving the problems of development or social and economic justice. This is perfectly true, of course; but unless the runaway human

[140] W. P. Mauldin et al., *A report on Bucharest*.

population is brought under control -- and soon -- the result will be catastrophe. *What kind* of catastrophe cannot be predicted, but numerous candidates have been discussed in this book: ecological collapses of various kinds, large-scale crop failures due to ecological stress or changes in climate and leading to mass famine; severe resource shortages, which could lead either to crop failures or to social problems or both; epidemic diseases; wars over diminishing resources; perhaps even thermonuclear war. The list of possibilities is long, and overpopulation enhances the probability that any one of them will occur. Population control may be no panacea, but without it there is no way to win.

CHAPTER 14
Changing American Institutions

The ecological constraints on population and technological growth will inevitably lead to social and economic system different from the ones in which we live today.

In order to survive, mankind will have to develop what might be called a steady state.

The steady state formula is so different from the philosophy of endless quantitative growth, which has so far governed Western civilization, that it may cause widespread public alarm.

--René Dubos, 1969

Mistrust of technology is an attitude that ought to be taken seriously. It has positive value in avoiding grave disasters.

--Roberto Vacca, 1974

Changing individual attitudes on population size in general and family size in particular is only part of the problem facing humanity today. This chapter and the next examine the need for institutional changes to meet the population-resource-environment crisis. Here we focus primarily on the institutions of the most influential country in the world. It is the United States

that in the past few decades has been the leader in humanity's reckless exploitation of Earth; it was also in the United States that the resistance to that exploitation first became well organized. It seems unlikely to us that disaster can be averted without dramatic changes in the structure of many American institutions -- changes that could support and consolidate gains in such areas as family size, resource conservation and environmental awareness that have already been made on the basis of transformed individual attitudes.

Many of the institutional problems discussed here also have relevance to other nations, especially other DCs that since World War II have emulated the United States in many respects. Readers in other countries, therefore, may find some of this text directly relevant, even though the focus is on the United States. In Chapter 15 we expand our outlook to examine international institutions. All these institutions must be altered -- and soon -- or they and society as we know it will not survive. Whether significant changes in attitudes can occur fast enough to affect humanity's destiny is an open question. In our discussion we have held to one overriding principle: today's problems cannot be solved by destroying the

existing institutions; there is neither the time nor the leadership to dismantle them completely and replace them with others. Today's institutions must be bent and reshaped but not destroyed.

No one is more acutely aware than we are of the difficulties and hazards of trying to criticize and comment constructively on such broad areas as religion, education, economics, legal and political systems, and the psychology of individuals and societies. We believe, however, that in order for people to translate into effective and constructive political action what is now known about the roots of the crisis, new, far-reaching and positive programs must be undertaken *immediately*.

In this chapter and the next, we therefore depart from the realm of relatively hard data in the physical, biological, and social sciences to embark on an exploration of the many other areas of human endeavor that are critically important to a solution of our problems. [1] In doing so we are making the assumption that many reforms are essential. The dangers of making the opposite assumption are beautifully set forth in the following quotation from biologist Garrett Hardin's article, "The Tragedy of the Commons":

It is one of the peculiarities of the warfare between reform and the status quo that it is thoughtlessly governed by a double standard. Whenever a reform measure is proposed it is often defeated when its opponents triumphantly discover a flaw in it. As Kingsley Davis has pointed out, worshippers of the status quo sometimes imply that no reform is possible without unanimous agreement, an implication contrary to historical fact. As nearly as I can make out, automatic rejection of proposed reforms is based on one of two unconscious assumptions: (i) that the status quo is perfect; or (ii) that the choice we face is between reform and no action; if the proposed reform is imperfect, we presumably should take no action at all, while we wait for a perfect proposal.

But we can never do nothing. That which we have done for thousands of years is also action. It also produces evils. Once we are aware that the status quo is action, we can then compare its discoverable advantages and disadvantages with the predicted advantages and disadvantages of the proposed reform, discounting as best we can for our lack of experience. On the basis of such a comparison, we can make a rational decision which will not involve the unworkable assumption that only perfect systems are tolerable.

RELIGION

Religion, broadly defined, would include all the belief systems that allow *Homo sapiens* to achieve a sense of transcendence of self and a sense of the possession of a right and proper place in the universe and a right and proper way of life. In short, everyone wants to feel important and in tune with a right-ordered world. The attempt to achieve a sense of well-being in these terms is so pervasive among human cultures that it may be counted as a necessity of human life. With religion so broadly defined, political parties, labor unions, nation states, academic disciplines, and the organized structure of the environment-ecology movement would have to be counted among our religious institutions. Certainly, representatives of all those groups have struggled to protect and propagate their views as assiduously (and sometimes as fiercely) in our time as Genghis Khan, the Christian Crusaders, or the Protestant Christian missionaries did in theirs. In this discussion, however, we limit our attention to those groups customarily called the world's great religions, the traditions of belief and practice belonging to members of the Judeo-Christian, Moslem, Buddhist, and Hindu traditions.

Religion must always be viewed in its two parts: the first and more readily evident element being the formal structure of authority and administration that in our Western tradition is called "the church;" and the second, more elusive, and in the long run more important element, the system of attitudes called, in the Western manner, "the faith." In our treatment of the two parts, we concentrate upon the relationship between organized religion and population control because that is the area where contemporary social needs and imperatives have most clearly come into conflict with cherished traditional values usually promulgated and supported by religions. Moreover, humane population control calls for the

[1]Many of these topics are treated in greater depth in Dennis C. Pirages and Paul R. Ehrlich, *Ark II: Social response to environmental imperatives*; its footnotes and bibliographies provide further access to the pertinent literature, especially in political science.

integration of contraceptive techniques into culturally accepted sexual practices, and sexual practice is the area of human activity that is typically most extensively regulated by taboo. Thus, the acceptance or rejection of birth control and various methods of carrying it out have been important issues in organized Western religion for several decades.

Our treatment of religious attitudes also focuses upon perceptions of the environment, because how an individual perceives and treats the world is determined by his or her overall view of his or her place in that world. The Christian concept of life in this world, as voiced by Saint Paul,

that "here we have no abiding city," for example, conceivably could help explain why some people show rather little concern for the long-term future of the global environment or for the well-being of future generations.

Most of our attention is on the Western, JudeoChristian religious tradition because it is primarily within that tradition that the population-resourceenvironment crisis has been engendered.

Organized Religious Groups and Population Control

Within the theological community in the Western world, there has recently been a heartening revolution in thought and action on such varied social concerns as the quality of life in urban areas, civil rights for minority groups, and the war in Vietnam. Since the late 1960s, environmental deterioration and the population explosion have become important concerns. Protestant, Catholic, and Jewish clergy have come more and more to the forefront of public activities in these areas, often at considerable personal sacrifice and risk.

Conspicuous among clergy who have risked their careers have been Catholic theologians who opposed the official pronatalist position of the Vatican. For example, Father John A. O'Brien, a distinguished professor of theology at Notre Dame University in Indiana, edited the excellent book *Family planning in an exploding population* in 1968. He also was a leader in criticizing Pope Paul VI's 1968 encyclical, *Humanae Vitae*, which reiterated the church's condemnation of contraceptives. Commenting on the encyclical, Father O'Brien wrote, "Since the decision is bound to be reversed by his [Pope Paul's] successor, it would be far more honorable, proper and just for the Pope to rescind it himself." [2] Ivan Illich, who renounced his priesthood after a controversy over birth control in Puerto Rico, wrote that the encyclical "lacks courage, is in bad taste, and takes the initiative away from Rome in the attempt to lead modern man in Christian humanism." [3] Thousands of others, from cardinals to lay people, have also spoken out. Since its publication, the encyclical has caused immense anguish among Catholics, millions of whom have followed their consciences and used contraceptives, often after a period of intense soul-searching. [4] Indeed, clergyman sociologist Father Andrew Greeley attributes the recent substantial erosion in religious practices and church support among American Catholics almost entirely to *Humanae Vitae*. [5]

Adamant opposition to birth control by the Roman Catholic Church and other conservative religious groups for many years helped delay the reversal in developed countries (including the United States) of laws restricting access to contraceptives and the extension of familyplanning assistance to LDCs. Support of outdated dogma among Catholic spokespeople still sometimes hinders effective attacks on the population problem in Catholic countries and in international agencies that support family-planning programs. Thus, as late as 1969, elderly Catholic economist Colin Clark claimed on a television program that India would, in a decade, be the most powerful country in the world because of its growing population! He also wrote, "Population growth, however strange and unwelcome some of its consequences may appear at the time, must be regarded, I think, as one of the instruments of Divine Providence, which we should welcome, not oppose." [6]

By the mid- 1970s, however, the influence of such persons was on the wane -- so much so that a reaffirmation by Pope Paul of his anti-population-control dogma at the 1974 World Food Conference in Rome was greeted by almost universal ridicule. Within the church, Pope

Paul's influence seems likely to decline as older members of the hierarchy are replaced by administrators more in touch with humanity and modern times. Growing numbers of priests and other clerics in the lower ranks of the hierarchy no longer condemn the use of contraceptives -- some even condone abortion under some circumstances, although the hierarchy is, if anything, even more rigidly opposed to that. A great many Catholic laymen are ahead of the Church in changing their attitudes; by the mid-1970s more than 80 percent of Catholics in the United States approved of the use of contraceptives. [7]

The new look in attitudes is typified by those of Catholic biologist John H. Thomas of Stanford University, who in 1968 wrote to San Francisco's Archbishop Joseph T. McGucken:

The Church must affirm that the birth rate must soon be brought in line with the death rate -- i.e., a growth rate of zero. This is the responsibility of all people regardless of race or religion. The Church must recognize and state that all means of birth control are licit . . . (it) must put its concern for people, their welfare, and their happiness above its concern for doctrine, dogma, and canon law . . . It is time that the Church stop being like a reluctant little child, always needing to be dragged into the present.

John Thomas was also a prime mover in promoting the Scientists' statement against the birth-control encyclical, which within five weeks in 1968 was signed by more than 2600 scientists. [8] He was joined by two other Catholic biologists, Dennis R. Parnell (California State University at Hayward) and Brother Lawrence Corey (St. Mary's College, Moraga, California) in mailing the statement with their endorsement to the approximately 150 Roman Catholic bishops in the United States.

Furthermore, it should not be forgotten that physician John Rock, who played a leading role in developing the contraceptive pill, is a Catholic. He also participated in the theological debate on the morality of birth control until the encyclical was issued, effectively squelching the debate.

Except for the Roman Catholic church, all major Western religious groups had by 1970 officially sanctioned "artificial" contraception, although some continued to oppose liberal abortion policies. Religious leaders of various faiths in the United States have helped overcome ancient cultural taboos related to reproduction by emphasizing the quality of human life rather than its

quantity. Protestant, Catholic, and Jewish theologians, for example, have been active in promoting sex education in schools, and many Protestant and Jewish theologians and lay people have supported liberal abortion policies. Bishop C. Kilmer Myers, of the Episcopal diocese of California, for example, in the late 1960s established the Ad Hoc Metropolitan Planning Group, which has been deeply concerned with the problems of population and environment. The Social Ministry of the Lutheran Church in America promulgated a highly enlightened policy on population in the 1960s; Methodist groups were in the forefront of abortion-law reform in the United States. Thus, there is good reason to hope that organized Western religious groups may become a powerful force in working toward population control worldwide, especially as the human suffering caused by overpopulation becomes more widely recognized.

Non-Western religions. The possible roles of nonWestern religious institutions in the population crisis are more problematical than that of Western religions. For example, within Islamic religion there is no organized, deep involvement in social problems, although Islamic scholars have tried to find religious justification for practicing birth control in some countries hard-pressed by exploding populations. There are at least 500 million Moslems in the world (roughly half the number of Christians), more than 95 percent of whom live in Africa and Asia, with high concentrations in such problem regions as Indonesia and the Indian subcontinent. Pakistan, by establishing a government-supported familyplanning program as early as 1960, made it clear that Moslem countries can attempt to solve their population problems without religious conflict. [9] Several other Moslem countries have since established family-planning programs and/or changed their laws to permit broader access to birth control. In the foreseeable future, however, it seems unlikely that Islam itself will become a positive force for population control.

---

[7]Greeley, *Catholic schools*.

[8]J. J. W. Baker, *Three modes of protest action*.

[9]M. Viorst, "Population control: Pakistan tries a major new experiment".

Much the same can be said of Buddhism, which -- if those who also subscribe to Shinto, Taoism, and Confucianism are also counted as Buddhists -- has perhaps 700 million adherents, most of them in Asia. The barriers to population control in Asia and the potential for accepting it both seem to be connected much more with social conditions than with religion. Therefore, it seems unlikely that changes in the religion would have any substantial effect on establishment of population policy, although religious support for small families might encourage acceptance of family planning.

Similarly, it is hard to picture Hinduism, as an entity, becoming a force in population control. More than 99 percent of the 450 million or so Hindus live in Asia, mostly in India. Like Buddhism, it is a rather heterogeneous, relatively noninstitutionalized religion. There is still considerable opposition to population control among Hindus, perhaps based more on medical beliefs, local superstitutions, and a sense of fatalism than on anything inherent in the religious structure.

For Westerners who favor population control, one of the best courses of action seems to lie in working with the already established religious groups to change people's attitudes toward population growth. In the rest of the world, the relative fragmentation of religious groups, their lack of hierarchic organization, and their psychosocial traditions would seem to limit their capacity to influence population control efforts.

Religious Attitudes and the Environment

In the United States, the unorthodox but constructive and quasi-religious attitudes first expressed widely in the 1960s by members of the whole-Earth, hippie movement may well help save the environment. The initial phase of the hippie movement was characterized by a groping and testing that produced, among other things, the dangerous macrobiotic diet and the horror of the Manson family. Aside from such excesses, however, the hippies borrowed many religious ideas from the East, particularly Zen Buddhism, combined them with the collectivist, passivist element from Christian tradition, and attempted to forge a code based on close personal relationships, spiritual values, a reverence for life, group self-reliance, and an abhorrence of violence. By the mid-1970s this code had become well established in a more mature and praiseworthy form that might be called the independence movement. People in that movement are attempting to find simpler, more ecologically sound modes of existence, and to reduce their dependence on fancy, nonessential, and vulnerable technological gimmickry. Their unofficial publications such as *Mother Earth News* and *CoEvolution Quarterly* abound with suggestions for disconnecting oneself from the "effluent society." If any one idea binds members of the movement together, it is the belief -- essentially religious -- that human beings must cooperate with nature and not attempt to subdue nature with brute force.

Many people in our society are unhappy with these attitudes, which go against long-cherished and religiously sanctioned political and economic beliefs. They feel that turning away from a consumer orientation has grave implications for the future of the economy. Others see in the independence movement the vanguard of a new social revolution that could lead to a very different, far better society.

Lynn White, Jr., professor emeritus of history at the University of California, Los Angeles, and past president of the American Historical Association, has suggested that the basic cause of Western society's destructive attitude toward nature lies in the Judeo-Christian tradition. He pointed out, for instance, that before the Christian era, people believed trees, springs, hills, streams, and other objects of nature had guardian spirits. Those spirits had to be approached and placated before one could safely invade their territories: "By destroying pagan animism, Christianity made it possible to exploit nature in a mood of indifference to the feelings of natural objects." [10] Christianity fostered the basic ideas of "progress" and of time as something linear, nonseparating, and absolute, flowing from a fixed point in the past to an end point in the future. Such ideas were foreign to the Greeks and Romans, who had a cyclical concept of time and did not envision the world as having a beginning. Although a modern physicist's concept of time might be somewhat closer to that of the Greeks than to that of the

[10] The historical roots of our ecological crisis.

Christians, the Christian view is nevertheless the prevalent one in the Western world: God designed and started the universe for the benefit of mankind; the world is our oyster, made for human society to dominate and exploit. Western science and technology thus can be seen to have their historical roots in the Christian dogma of humanity's separation from and rightful mastery over nature.

Europeans held and developed those attitudes long before the opportunity to exploit the Western hemisphere arrived. The frontier or cowboy economy that has characterized the United States seems to be a natural extension of that Christian world view. Therefore, White claimed, it may be in vain that so many look to science and technology to solve our present ecological crisis:

Both our present science and our present technology are so tinctured with orthodox Christian arrogance toward nature that no solution for our ecologic crises can be expected from them alone. Since the roots of our trouble are so largely religious, the remedy must also be essentially religious, whether we call it that or not.

A number of anthropologists and others have taken issue with White's thesis, pointing out that environmental abuse is by no means unique to Western culture, and that animism had disappeared, at least in western Europe, before Christianity was introduced. As examples they cite evidence of ancient and prehistoric environmental destruction, such as the human-induced extinction of Pleistocene mammals and the destruction of the fertility of the Near East by early agricultural activity, as well as the behavior of non-Western cultures today.

Geographer Yi-Fu Tuan of the University of Minnesota observed that there is often a large gap between attitudes toward the environment expressed in a religion or philosophy and the actual practices of the people who profess those attitudes. [11] While Chinese religions, for example, stressed the view that man was a part of nature (rather than lord of it) and should live in harmony with it, the Chinese did not always live by that belief. Concern for the environment, especially preserving forests and protecting soils, were expressed throughout Chinese history, but Yi-Fu Tuan suggests that this may often have been in response to destruction that had already taken place. The fact that China was a complex civilization complete with a bureaucracy and a large population doubtless militated against fulfillment of those ideals. By the twentieth century, China's once-plentiful forests had been nearly destroyed to build cities and clear land for agriculture. All that remained in most areas were small patches preserved around temples. Ironically, the present government, which explicitly rejects the traditional religions, has attempted to restore the forests on a large scale. [12]

Lewis W. Moncrief of North Carolina State University, who might be described as an environmental anthropologist, feels that the religious tradition of the West is only one of several factors that have contributed to the environmental crisis. [13] Along with some other anthropologists, he has suggested that an urge to improve one's status in society is probably a universal human characteristic and that expressing this urge through material acquisitiveness and consumption of resources is, if not universal, at least common to a great variety of cultures. Perhaps what is unique about Western culture in this regard is the degree of its success.

Moncrief postulated several factors that he felt were just as influential as the Judeo-Christian outlook in determining European and North American behavior toward the environment. The first were the development of democracy and the Industrial Revolution, which together provided individual control over resources (if only a family farm) for a far greater proportion of the population than before and simultaneously provided the means to exploit those resources more efficiently. The existence of a vast frontier fostered the belief in North America that resources were infinite; all of our wasteful habits derive from that. Moncrief thinks it is no accident that the first conservation movement appeared just as the frontier was closing; Americans suddenly and for the first time began to realize that their resources were, after all, finite.

In 1893, moved by a remark from the 1890 census

---

[11]Our treatment of the environment in ideal and actuality.

[12]For an overview of present Chinese attitudes, see L. A. Orleans and R. P. Suttmeier, the mass ethic and environmental quality, *Science*, vol. 170, pp. 1173-1176 (December 11, 1970), a related account of Japanese attitudes toward the environment is Masao Watanabe, *The conception of nature in Japanese culture*.

[13]The cultural basis for our environmental crisis.

about the disappearance of public land and the consequent disappearance of the frontier, Frederick Jackson Turner, then at the University of Wisconsin and subsequently at Harvard, observed:

American social development has been continually beginning over again on the frontier. This perennial rebirth, this fluidity of American life, this expansion westward with its new opportunities . . . furnish the forces dominating American character. [14]

A generation earlier, E. L. Godkin, editor of the *Nation*, had written that the American frontier population had "spread itself thinly over a vast area of soil, of such extraordinary fertility that a very slight amount of toil expended on it affords returns that might have satisfied even the dreams of Spanish avarice." [15]

Traditional North American (and, to some extent, European) attitudes toward the environment thus are not exclusively products of our religious heritage, although that doubtless played an important part. These attitudes may just spring from ordinary human nature, which in Western culture was provided with extraordinary social, political, technical, and physical opportunities, particularly connected with the nineteenth-century American frontier. Such opportunities were bound to engender optimism, confidence in the future, and faith in the abundance of resources and the bounty of nature. That they also produced habits of wastefulness and profligacy was not noticed. Past institutions in the United States rarely dealt with environmental problems; if they were recognized at all, they were usually considered to be someone else's responsibility.

In the twentieth century, as the growing population became increasingly urban and industrialized, the environmental effects multiplied, and the nation was rather suddenly

confronted with a crisis. How today's Americans ultimately resolve the environmental crisis will depend on much more than changes in philosophical outlook, but such changes unquestionably must precede or at least accompany whatever measures are taken. Individual conduct is clearly capable of being modified and directed by an appropriate social environment -- the change in reproductive habits in the United States testifies to that, as does the great increase in environmental consciousness. Unfortunately, the environmental problem may prove more difficult because it requires changing more than the attitudes and behavior of individuals: those of firmly established, powerful institutions -- primarily business and governmental organizations -- must also be changed.

How large a role organized religion may play in guiding the needed changes in individual attitudes toward the environment or in influencing the behavior of other institutions is still uncertain. Many religious groups have already shown leadership, including some already mentioned in connection with populationrelated issues. A particularly hopeful sign was the concern expressed in January 1976 by the National Council of Churches about the ethics of using and spreading the technology of nuclear power, and the discussion promoted by the World Council of Churches on the nuclear issue and on the relation of energy policy to the prospects for a "just and sustainable" world. [16]

Ecological Ethics

Many persons believe that an entirely new philosophy must now be developed -- one based on ecological realities. Such a philosophy -- and the ethics based upon it -- would be antihumanist and against Judeo-Christian tradition in the sense that it would not focus on an anthropocentric universe. [17] Instead, it would focus on human beings as an integral part of nature, as just one part of a much more comprehensive system.

This is not really a new perspective. In one sense, Western philosophy has been a continuous attempt to establish the position of Homo sapiens in the universe, and the extreme anthropocentrism of thinkers like Karl Marx and John Dewey has been strongly attacked by, among others, Bertrand Russell. [18] Russell, for example,

[17]See Frank E. Egler, *The way of science: A philosophy of ecology for the layman*; and George S. Sessions, *Anthropocentrism and the environmenttal crisis*. The latter is a good, brief summary with a useful bibliography.

[18]*A history of Western philosophy*, the debate is summarized in Sessions, Anthropocentrism.

pointed out Marx's philosophical closeness to classical Judeo-Christian thought:

His purview is confined to this planet, and, within this planet, to Man. Since Copernicus, it has been evident that Man has not the cosmic importance which he formerly arrogated to himself . . . There goes with this limitation to terrestrial affairs a readiness to believe in progress as a universal law . . . Marx professed himself an atheist, but retained a cosmic optimism which only theism could justify. [19]

The concern of ecological ethics is not primarily that of considering the human position in the cosmos, but rather of considering the roles played by human beings in the ecosphere. It takes a view diametrically opposed to the position expressed by Aristotle 2300 years ago: "Now if Nature makes nothing incomplete, and nothing in vain, the inference must be that she has made all animals for the sake of man." [20]

From the standpoint of ecological ethics, the world is thus seen to be not humanity's oyster but a complex system that supports us, of which we are a part, and toward which we have moral responsibilities. Ethical theorist Joseph Margolis has written:

But it may well be that the ethical visions of the future -- assuming the earth has a future-- will be discarded as beneath debate if they do not include, centrally, an account of the ethics of the human use of the inanimate and non-human world. Such a discipline . . . might be called moral ecology. . . . [21]

Whether or not such a philosophy is incorporated into religious dogma is immaterial. What counts is that something like it has influenced many Americans and Europeans already, and may come to be accepted in other places as well. (In some cultures, of course -- some native American world views and some aspects of Hinduism come to mind -- the idea of humanity as a part of nature has always predominated.) The sooner an ethic based on respect for the natural world can be adopted, the better. The beneficiaries will be not only ourselves but our children and grandchildren.

The Conservation Movement

The fascination and profound emotions -- essentially religious feelings -- aroused in many people by wilderness areas, wildlife, and beautiful natural scenery are not easily explained to those who do not share them. Disparate beliefs and attitudes are obvious every time conservationists find themselves defending aesthetic values against people who are equally dedicated to "progress." This divergence of views was elegantly summarized by the brilliant French anthropologist Claude Levi-Strauss, who noted that any species of bug that people spray with pesticides is "an irreplaceable marvel, equal to the works of art which we religiously preserve in museums." [22]

For many years now, people in the conservation movement have fought individually and in groups to halt the extinction of animal species and the destruction of the last vestiges of the primitive areas of Earth. Some of the campaigns conducted by such organizations as the Sierra Club, the Audubon Society, the Defenders of Wildlife, the Wilderness Society, and the Nature Conservancy in the United States, and by the World Wildlife Fund and similar organizations in

other countries, [22a], have been successful. It is becoming clear, however, that in the long run the conservation movement as a whole has been fighting a losing battle.

Perhaps the most obvious reason the battle is being lost is that conservation is a one-way street: each organism or place conserved essentially remains in perpetual jeopardy. Each gain is temporary, but every loss is permanent. Species cannot be resurrected; places cannot be restored to their primitive state. Consequently, even if the conservationists were evenly matched against the destroyers, the battle would probably remain a losing one. But, of course, the battle has been far from even. Powerful economic interests and government agencies, pushed by population pressures, have promoted the development of every possible inch of the United States by building dams in desert canyons, driving roads through the remaining wilderness areas, cutting the last

of the primeval forests, drilling for oil on the northern slope of Alaska, and so on. It is a tribute to the conservationists, past and present, that any of our primitive areas remain relatively unspoiled. Political and financial power tend to be arrayed against conservation, and, as people increase and resources dwindle, the situation seems bound to deteriorate further. In many parts of the world the situation is worse than in the United States; in a few it is better.

There are encouraging signs that a new thrust is appearing in the conservation movement. Growing numbers of people have realized that conservation is a global problem, that in the long run it is not enough to preserve such isolated treasures as a grove of redwood trees. If global pollution causes a rapid climatic change, the grove cannot long survive. Many conservationists now recognize that if the growth of the human population is not stopped, and the deterioration of the planetary environment is not arrested, *nothing* of value will be conserved.

This understanding and the growing general public awareness of the problems of the environment have given rise to a number of new organizations. Some of them, like Friends of the Earth (FOE), are more militant offshoots of older conservation groups. Others, including Environmental Action (which grew from the organization that sponsored the first Earth Day in 1970) and Ecology Action, are new. Zero Population Growth (ZPG) is primarily concerned with the population problem but is also interested in the environmental consequences of it. ZPG, one branch of the Sierra Club, Environmental Action, and FOE have foregone the tax advantages of an apolitical posture in order to campaign and lobby for their goals, frequently combining their efforts on issues of common concern. They also cooperate in environmentalist lawsuits (see "The Legal System," below) through organizations such as The Environmental Defense Fund (EDF) and the Natural Resources Defense Council (NRDC). Such organizations generally differ from

many of the older conservation groups in being more oriented to humanity as an endangered species than to preserving wilderness and wildlife only for their aesthetic and recreational values. Sister organizations of FOE, as well as ZPG, have been established in other countries.

In Europe, Australia, and New Zealand, the environmental movement has established its own political parties, known in Britain as the Ecology Party, in France as Ecologie et Survie, in New Zealand as the Values Party, etc. These parties have succeeded in winning seats in Britain's Parliament and gaining significant percentages of the vote in several countries. [22b] In March 1977, the ecology party in France won a nationwide average of 10 percent of the vote in municipal elections. In some towns in Alsace (where the party originated) they won 60 percent. [22c]

It seems likely that conservationist and environmental organizations will become still more militant and more united -- especially in their global concerns. While important local battles must continue to be fought, more general programs of public education and political action should become predominant. Obviously, it is no longer necessary to plead for conservation only on aesthetic or compassionate grounds, since the preservation of the diversity of life and the integrity of the ecological systems of Earth is absolutely essential for the survival of civilization.

SCIENCE AND TECHNOLOGY

For many people, science and technology have taken on the aspect of a religion. How often one hears statements beginning, "any society that can send a man to the moon can. . . ." and ending with some problem -- usually immensely more complex and difficult than space travel -- that science and technology are expected to solve! [23] The population-food imbalance is a common candidate; others are various types of pollution or other ecological problems.

Three things are generally wrong with these statements of faith. First, science and technology have not yet reached the point relative to those problems that they had reached relative to the man-on-the-moon project by

---

[22b] Edward Goldsmith, "Ecology-the new political force".

[22c] "Ecologists emerge as a potent force in French election", *New York Times*, March 20, 1977.

[23] One book on the human predicament written from this point of view (but in which the science is often very weak) is John Maddox's *The doomsday syndrome*. See the retrospective review written three years later by John Woodcock, Doomsday revisited.

1955. The general outlines of a solution are not clear to all competent scientists in the pertinent disciplines. Second, and equally important, there is no sign of a societal commitment to a crash program to solve those nonspace problems. Third, any solutions to those problems would spell significant changes in the ways of life of millions of people, which the space program did not.

The public, indeed, has developed a touching but misplaced faith in the ability of science and technology to pull humanity's chestnuts out of the fire. There is not the slightest question that

with clever and cautious use of scientific and technological resources, a great deal of good could be accomplished. But can the required amount of cleverness and caution be found? Despite enormous scientific advances during the past thirty years, it is perfectly clear that the *absolute amount* of human misery has increased (because of the enormous growth in the numbers of poverty-stricken human beings), while the chances that civilization will persist have decreased. There has been an abundance of science and technology, but they have been unbalanced and out of control.

Priorities and Planning

It has been estimated that more than 400,000 scientists and engineers -- about half the technical community of the world -- are working on weapons of war. Each year, military research and development worldwide cost about $25 billion, some 4 times what is spent on medical research (and perhaps 1000 times that spent on ecological research). [24] Medicine and public-health measures have attacked the death rate with vigor but for a long time ignored the birth rate, in the process threatening humanity with unprecedented catastrophe. Physics has produced nuclear and thermonuclear weapons, a legacy so weighty on the minus side of the balance that it is difficult to think of any serious pluses with which to counter it. Biology has provided weapons for biological warfare and has seen many millions of dollars poured into molecular genetics, a field offering little immediate improvement in human welfare but possessing great potential for curing or preventing inborn defects or for curing cancer, and the like. The greatest contribution of molecular genetics to human welfare has been the Ames test (Chapter 10), which, ironically, will help protect humanity from the "triumphs" of organic chemistry! Meanwhile, support for environmental studies has been relatively insignificant, despite repeated warnings by ecologists for more than a quarter of a century that human action was threatening to destroy the life-support systems of the planet. The behavioral sciences -- still in their infancy -- have also languished despite their potential value in helping to solve human problems.

Most of the great "advances" in technology, from DDT and X-rays to automobiles and jet aircraft, have caused serious problems for humanity. Some of those problems would have been difficult to anticipate (Box 14-1), but most were foreseen, were warned against, and could have been avoided or ameliorated with sensible societal planning. The question now is, how can such planning be done in the future so as to minimize the unfortunate consequences of technological "advances" made thus far -- to say nothing of those yet to come?

It is clear from the records of organizations such as the American Medical Association and the AEC (now the Nuclear Regulatory Commission, NRC), and from statements by technological optimists and scientific politicians that scientists (like other groups in our population) cannot be relied upon to police themselves. Some way must be found to foster greater participation by other segments of society in the major decison-making processes affecting science and technology. This is essential, of course, to the survival of society, but it is also important as protection for scientists themselves. Burdens of guilt, like those borne by the physicists involved in developing atomic weapons, must be avoided wherever possible, or at least more broadly shared.

Controls

We are not in a position here to propose a detailed structure for controlling science and technology, but we can suggest some general directions. Government agencies such as the National Science Foundation and

[24]See Stockholm International Peace Research Institute, "Why arms control faiilt". Of course, the causes of the lack of balance and control are complex, and we do not have space to discuss them here. For an introduction to the subject, see Robin Roy, "Myths about technological change", *New Scientist*, May 6, 1976, pp. 281-282.

Box 14-1 Risks, Benefits, and New Technologies

As previously indicated, it is common for unforeseen difficulties to arise with new technologies, and the more grandiose the technological enterprise, the greater the problems seem to be. Supertankers provide a classic example of the difficulties encountered in scaling up an already hazardous technology. * Oil tankers have always been prone to accident, but the frequency (and environmental consequences) of accidents have escalated dramatically as their size has increased. In 1945 the largest oil tankers were 18,000 deadweight tons (dwt). In the early 1960s the maximum size had risen to 100,000 dwt and by the end of that decade had exceeded 300,000 dwt. In the 1970s planners were looking forward to constructing tankers in the megaton range.

Both the stresses imposed upon the structures of the larger ships and their different handling characteristics were unanticipated. Supertankers sometimes crack when being loaded and show a distressing tendency to disintegrate spontaneously at sea. The huge cleaning machines used to wash out their tanks after unloading apparently create minithunderstorms in the cavernous spaces. These thunderstorms even produce lightning, which can detonate oil fumes if the fume-air mixture is neither too rich nor too lean, blowing the tank or the ship apart.

The hydrodynamic properties of the huge ships are such that they must begin "putting on the brakes" three miles before reaching a full stop. They are difficult to maneuver and their captains require special training. Yet because of their great draft they are often operated in waters where their keels extend to within two feet of the charted bottom. This is a dangerous practice both because hydrodynamic factors reduce maneuverability in shallow water and because in some areas the depth of the bottom is continuously changing. These factors, among others, have led to a rash of collisions and groundings, often with disastrous results. For example, in 1970 the relatively small supertanker *Polycommander* ran aground near the Spanish coast and ignited. Some 16,000 tons of oil burned, generating a fire storm whose updrafts carried oil high into the atmosphere and created a black rain along the coast, doing extensive damage to crops, livestock, homes, and gardens.

Some of the difficulties with supertankers can be blamed on dangerous economies undertaken by the owners. Ships can be designed that are stronger, more maneuverable, and more resistant to

explosion than most of those now in service. And personnel on many ships could be much better trained; many officers running ships registered under flags of convenience such as Panama and Liberia are not properly certified, and some have proven hopelessly incompetent. There is little doubt, either, that the Intergovernmental Maritime Consultative Organization (IMCO), a specialized United Nations agency, has proven ineffective as a regulatory body.

But the familiar saga of profits-before-safetyor-environment, so characteristic of the energy industry, is not the whole story. The unanticipated characteristics of the big ships threaten both safety and profits, since the disaster rate has pushed insurance premiums toward uneconomic levels. What will happen as these ships age (they were designed to be written off after ten years) remains to be seen. The prospects are not cheering.

One does not, however, have to turn to such exotica as the supertankers to see the impact of the unexpected in new technologies. The heavily regulated safety-oriented aviation industry provides more than enough examples. A classic was the series of fatal crashes of *De Havilland Comet* jets, caused by unanticipated fatigue failures of the cabin under pressurization, that lost the United Kingdom its lead in the race to develop passenger jet aircraft. The success of the United States industry (and its fine safety record) was due in no small degree to the Boeing 707, which, unlike the Comet, was not a novel design but had behind it a long operating history with military jet tankers of similar size and configuration.

Design flaws have often led to one or more fatal crashes of new transport aircraft. Gas leaking into heating systems during transfer from one tank to another destroyed a Douglas DC-6 with the loss of fifty-two people, and it nearly destroyed another before the problem was identified and corrected. Unexpected stresses transmitted from propeller to wing caused the disintegration in midair of two Lockheed Electra propjets. [**] After correction of the problem, the aircraft had a fine safety record in civil and

---

[*] The discussion of tankers is based on N. Mostert's fascinating *Supership* and D. F. Boesch et al., *Oil spills and the marine environment*, Ballinger, Cambridge, Mass., 1974.

[**] Stephen Barlay, *The search for air safety*. The following material on T-tail jets is largely from this source also. For a balanced, readable account of aviation accidents in the prejet age, see Robert J. Serling, *The probable cause*.

military service. More recently, insufficient strength in the cabin floor, which buckled during decompression after an improperly secured baggage door opened, led to the fatal crash of one of the new wide-bodied jet airbuses, and the nearcrash of another. The buckling of the floor rendered control cables running beneath it inoperable.As with the supertankers, the human factor often enters into disasters associated with new aviation technology. The introduction of Ttailed short-haul jets such as the Boeing 727, the Douglas DC-9, the BAC 111, and the HawkerSiddeley Trident brought into service aircraft with high sink rates, designed for short-field operations. A series of Boeing 727 accidents at first caused doubts about its fundamental airworthiness, but careful analysis of the accidents and the aircraft's subsequent excellent record for safe operation indicated that some pilots just were not able to make the transition to handling the new jets. It was also discovered that some design characteristics of 727s, such as weakness in

the fuel lines that run under the floor, had increased the lethality of "survivable" crashes. New training standards and structural modifications helped solve the problems.Similarly, the safety record of the highly regulated nuclear power industry shows clearly how the unexpected must be expected when dealing with novel technologies. Although no vast disasters have yet occurred in the use of fission reactors to generate power, there has been an enormous number of minor accidents and near-misses--many arising from totally unanticipated sources. Workers make improper welds, inspectors set fires while using candles to detect air leaks, cooling systems fail to perform as they are supposed to, and parts added to increase safety tear loose to cause accidents that endanger the lives of hundreds of thousands of people. (For a more extensive discussion, see Chapter 8.)Experience with complex technologies, including those in the extremely safety-conscious aviation and nuclear power industries, gives a message loud and clear. The application of top engineering experience, the use of redundant systems, limiting operations to highly trained professionals, and strict government regulation are not enough to prevent accidents. No "fault tree" analysis can foresee all possible branches of the tree, all the conceivable "common-mode" failures. No regulatory body can ride herd on every operator day and night, discover his or her mental quirks, monitor his or her levels of boredom, stress, dissatisfaction, physical and mental health -- all of which are factors in determining how safe the operator's performance will be.We must face it -- unsinkable Titanics sink, earthquake-proof overpasses guaranteed to Force 8 on the Richter scale collapse in earthquakes orders of magnitude less severe; foolproof rapid-transit control computers get fooled; and cable-car cables that engineers say don't snap, do snap. [†] Perfect safety is a myth. Therefore, when any massive new technology is introduced, its presumed benefits must be weighed against possible risks. And, when the risks are evaluated, they can never be presumed zero.When looking at risks, many complex factors other than scale must be considered:

> Concentrated versus distributed deaths and injuries. It appears, for instance, that roughly 50,000 distributed deaths on U.S. highways is a risk acceptable to the public. But 50,000 deaths annually concentrated in a single nuclear power plant accident seemingly would not be. Other factors, such as perceived availability of alternatives and degree of personal control, may well enter here also.
> Immediate toxicity versus long-term toxicity. How does society balance 100 deaths from acute poisoning against the induction of 500 cancers that will kill twenty years later, or 5000 birth defects in future generations?
> Direct effects versus indirect effects. How, for example, should society evaluate the impact of pollution of a river by an industrial plant on the water supply of a town downstream compared to its effect on the food supply of that town through reduction of the fisheries productivity of the sea?
> Irreversibility. How much should the reversibility of events be weighed in a riskbenefit analysis? Many forms of air pollution are reversible; if injection of material into the atmosphere were stopped, the atmosphere would soon cleanse itself. Some other pollutants are readily degraded

[†] Engineer Arturo Tanesini, commenting on a cable car accident in Italy that killed forty-two people after a supporting cable snapped, said, "supporting cables just don't snap," *Honolulu Advertiser*, March 11, 1976.

by ecological systems. On the other hand, strip mining often permanently destroys the land, many pollutants are extremely slow to degrade, and the toxic effects of a nuclear power plant accident could persist for half a million years.
Uncertainty. How does one evaluate the unknowns?

We do not pretend to have answers to these complex questions, of course, especially when both benefits and risks tend to be hard to identify, let alone quantify early in the development of a technology. We do suggest, however, that the tendency to develop and deploy technologies helter-skelter with little or no public airing -- at least until capital and other commitments are such that the economics of an industry become a part of the issue -- should be controlled somehow. In particular, the benefits should be most carefully considered, since in certain situations the maximum benefits may be rather clear while the maximum risks may be utterly unanticipated. A good example is the use of aerosol cans with fluorocarbon propellants to spray underarm deodorants. The risks of inhaling a fine mist of deodorant are not clear (but in our opinion it is not a good idea to inhale regularly a fine mist of anything except, perhaps, water), and the risks to the ozone layer are, at this writing, in some dispute. But it seems unlikely that the benefits of this sort of deodorant application (in comparison to many others) would be considered by a normal person to be worth any risk to life or health or to the integrity of Earth's ecological systems.

National Institutes of Health regularly employ ad hoc committees and panels of scientists to evaluate research programs and individual research projects. Universities also on occasion use such groups to evaluate programs or departments. Ad hoc panels of nonscientists might be integrated into these systems, drawn perhaps from citizens serving their sabbaticals (see *"Education"* below). Such panels could both advise agencies directly and report to a paragovemmental central body (perhaps elected), empowered to intervene whenever it was felt that the public interest was endangered. This power would extend to research under any auspices -- government, military, university, or industry. The central body could also be charged with continually informing both government and the public of pertinent trends in science and technology.

Increased awareness and scrutiny of science and technology will not, in themselves, suffice. Although laymen can become very knowledgeable about science and technology, as the performances of several congressmen involved in appropriations for scientific and technical projects have demonstrated, it is often very difficult or impossible for individuals, whether scientists or not, to foresee the consequences of certain trends. A second element is therefore required in the control system: an apparatus -- possibly in the form of research institutes - concerned solely with such assessment and reporting to the central body suggested above, as well as to the general public. Perhaps a set percentage of all funds used in government, university, and industrial research should be assessed for the support of those organizations, which should be kept strictly independent of each of those three interests.

Some of the work that might be done by such institutes would be an extension of the sort of programs now being run by systems ecologist K. E. F. Watt's group at the University of California at Davis, by systems analysts Jay W. Forrester of the Massachusetts Institute of Technology, and Dennis and Donella Meadows of Dartmouth. Watt has forecast the dismal

consequences of continuing various prevailing strategies of resource management and social policies. The Meadows, Forrester, and their colleagues have shown most convincingly that many of the various proposed courses of action may have unexpected -- and often very undesirable -- results. The studies of this group were made familiar to the world by the publication of *Limits to Growth* [25] (see Box 12-2).

In addition to such broad-scope evaluations as those,

The whole question of the evaluation of hazards is considered in an important book by W. W. Lowrance, *Of acceptable risk: Science and the determination of safety* (Kaufmann, Los Altos, Calif., 1976.)

[25] Potomac Associates, Washington, D.C., 1972.

some research institutes need to be investigating and reporting on much more detailed questions. For example, is medical research being done with adequate attention to the needs of all segments of the population and to birth control as well as death control? Are the benefits and risks of the breeder reactor being studied in proper depth? What are the possible dangerous consequences of further investigating the properties of a given virus or biocidal compound?

These questions have been settled largely by the scientific community in the past, with results that can most charitably be described as mixed. [26] For a long time the thrust in research was that whatever could be tried should be tried. Physicists exploded the first atomic bomb after Germany had been defeated and Japan's defeat was a certainty, *although some of them apparently thought at the time there was a nonzero chance that the explosion would destroy all life on Earth*. [27] It is difficult to find parallels, outside nuclear weaponry, displaying quite this degree of willingness to risk total environmental disaster, but traces of it arguably are present in proposals to "wait and see" what the consequences of assaulting the ozone layer with fluorocarbons or SST fleets will be.

On the bright side, microbiologists Paul Berg and Stanley Cohen of Stanford and Herbert Boyer of the University of California in mid-1974 called on their colleagues to bring to a halt research on recombinant DNA, studies involving transfers of genetic material from one species to another. [28] They recognized that hybrid microorganisms could cause extraordinarily virulent infectious disease and that the experimental work could conceivably lead to the spread of resistance to antibiotics or to the escape of bacterial strains carrying oncogenic (cancer-inducing) viruses. A distinguished molecular biologist, Robert Sinsheimer, has written:

Could an *Escherichia coli* strain [a variety of a ubiquitous bacterial resident on the human digestive tract] carrying all or part of an oncogenic virus become resistant in the human intestine? Could it thereby become a possible source of malignancy? Could such a strain spread throughout a human population? What would be the consequence if even an insulin-secreting strain became an intestinal resident? Not to mention the more malign or just plain stupid scenarios such as those which depict the insertion of the gene for botulinus toxin into *Escherichia coli*? [29]

In early 1975 an international scientific meeting established a set of safety principles under which such research could be continued. The scientists at the meeting concluded that the more dangerous experiments should be deferred until special "crippled" strains of organisms could be developed -- that is, strains with a very low probability of surviving outside the laboratory (experience has shown that there is no such thing as an "escape-proof" microbiological laboratory). Some of the scientists, however, argued against social control of the experiments, claiming an absolute right to free inquiry. Since that meeting, various attempts have been made to draft rules that would permit doing this dangerous research, and there has been continuing controversy. [30] In these cases, scientists themselves have assessed the risks and then "voted" for all of humanity. With regard to the atomic bomb, the possible savings in American (and Japanese) lives by shortening World War II may have come into the calculus, and perhaps also the thought that sooner or later someone else would blow up an A-bomb without knowing *for sure* that it would not destroy the planet. But would the people of the planet (to say nothing of the other living organisms) have voted yes to taking, say, a one-in-a-million chance on oblivion in order to speed victory for the United States in World War II? (That the chances of killing all life on the planet turned out to be zero is beside the point -- the scientists involved were not sure of that at the time.)

---

[26] See, for example, the contrasting views of F. J. Dyson, The hidden cost of saying "no!"; and P. R. Ehrlich, The benefits of saying "yes."

[27] N. P. Davis, *Lawrence and Oppenheimer*. There is no doubt, in light of present knowledge of nuclear reactions, that the chance of igniting the atmosphere with a nuclear bomb and thereby extinguishing all life on Earth is truly zero. A completely persuasive case on the point is made by H. A. Bethe, "Ultimate catastrophe?" *Builetin of the Atomic Scientist*, June 1976, pp. 36-37. Bethe's further contention, however, that the scientists on the nuclear bomb project were completely sure of this in 1945, is not persuasive.

[28] P. Berg, et al., "Potential biohazards of recombinant DNA molecules".

[29] Troubled dawn for genetic engineering. The article also contains a good, brief, layperson's introduction to the technology of DNA manipulation.

[30] Sinsheimer, Troubled dawn; Nicholas Wade, Recombinant DNA: NIH Group Stirs storm by drafting laxer rules; Bernard Dixon, Recombinant DNA: Rules without enforcement?

Similarly, in the case of recombinant DNA, although scientists seem to be acting much more responsibly, we must still ask whether they are the appropriate ones to make the decision. No laboratory safeguards can guarantee that an accidental escape will never occur. Are the possible benefits to medicine and agriculture of this research worth any risk of releasing a serious plague or cancer-inducing organism? We do not know the answer, but we think the franchise on the decision should be extended to include at least representatives of those who will be taking the risks and (perhaps) receiving the benefits.

The Science Court

One danger in allowing scientists to decide an issue for society is that often the specialists in a field disagree violently on the proper course of action for society to take, even though they may

have no serious disagreement on the known salient facts. For example, qualified scientists have been assembled on both sides of issues such as whether to develop the SST, ban the use of pesticides and aerosols, or develop nuclear power, to name a few. As Stephen Schneider and Lynne Mesirow observed regarding the SST battle:

An interesting point here is that most of the bitter scientific antagonists in the SST debate were probably in far greater agreement on what was known and unknown scientifically, and on the odds that state-ofthe-art estimates would be correct, than they were over whether the evidence justified opposition to the planes. That is, the interpretation of the weight of the evidence that guided their opposition or support was based not only on the scientists' technical knowledge of the issues, but also on their *personal* philosophies -on whether or not they wanted the SSTs and on whether they thought the benefits of the project were worth the risks of ignoring the worst possibilities. This is not to suggest that most testimony was deliberately misleading, but rather that scientists, like most people, shade to some extent their perception of the merits of conflicting evidence with the shadow of their personal philosophy. . . . The issues facing future generations are too critical to permit the technical components to be obscured in attacks on the personal philosophies of experts. . . . [31]

As they pointed out, some mechanism is needed so the public and decision-makers can separate the technical opinions of scientists from their political opinions.

One suggestion for opening up the process of ethical decision-making in science has been put forward by physicist Arthur Kantrowitz. [32] He proposed that in science policy disputes (such as those over SSTs and ozone, DDT and ecosystems, the risks and benefits of recombinant DNA research) the technical aspects of the cases be, in essence, tried in a scientific court. The first step would be to separate the scientific from the moral and political questions. What *might* be done with genetic engineering technology is a disputable scientific question, in principle soluble by experiment; what *should* be done is a political-moral question not in principle amenable to experimental solution.

Once the separation had been accomplished, then advocates of the different scientific points of view would "try" them before scientific judges. Thus, scientists convinced that DDT posed a serious threat to ecosystems could present their case, and the scientific advocates of the ecosystemic safety of DDT could present theirs. Each side could cross-examine the other. The judges would be selected for their neutrality on the issue, but would have the benefit of scientific training to help them evaluate the opposing views. The final step would be publication (within the limits of national security) of the opinions of the scientific judges.

It is easy for anyone familiar with scientific disputes to attack these proposals. In some cases the separation of scientific from moral and political questions is difficult. Is the question "Are blacks genetically less intelligent than whites?" scientific or moral? We would claim that the very posing of the question is a political act about which a moral judgment can be made -- but *in theory* it is a question amenable to experimental investigation.

A thornier problem would be selection of judges. In many cases today, disputes concern the negative direct or indirect effects of technology on humanity or on the

[31] *The genesis strategy*, pp. 188-189.
[32] See, for example, Controlling technology democratically.

ecosphere. The split within the scientific community on this is deep and bitter, and finding judges satisfactory to both technologists and environmentalists (for want of better terms) might often prove exceedingly difficult.

In spite of the difficulties, we support Kantrowitz's proposal for the test establishment of an institution for making scientific judgments as described above. The present methods of making such judgments are so bad that any promising alternative or modification deserves a chance. Installation of such a system will, as Kantrowitz points out, take place only over strong objections. It would threaten the vested interests of the politicians who wish to make politically expedient decisions supported by "facts" provided by their pet science advisers. And those scientists who have made lucrative careers and gained much personal power by telling politicians what they want to hear would not be pleased by the prospective dilution of their influence. [33]

Of course, even the most sophisticated scientific assessment apparatus could not avert all mistakes, but if it were backed by a growing feeling of social responsibility among scientists, it should be possible to improve the record greatly. In addition, ways must be found to increase public participation in technological decisionmaking -- a need that is being increasingly recognized. [34]

The remainder of the solution of learning to live with science and technology is to leave plenty of margin for error. For safety, we must learn to operate somewhat below our capability: not to push ourselves and Earth's ecosystems to the absolute limit, and not to do research in areas where a single slip can produce catastrophe.

Scientific Societies

Is there any way that scientific societies can improve the process of technology assessment? Unfortunately, scientists, like other professionals, have been slow to approach their social responsibilities corporately. For instance, the paramount scientific organization in the United States is the quasigovernmental National Academy of Sciences (NAS). Being elected to that organization is a high honor for a research scientist, and committees operating under its aegis often perform excellent studies on topics of broad interest to both scientists and society as a whole. Unfortunately, however, the NAS suffers from a number of difficulties that make some of its work suspect and often give the public an erroneous impression of its conclusions. [35]

First of all, the NAS, under its charter, is advisory to the government, and as a result its studies are often funded by government agencies. This has at times led to results being colored or suppressed. Similarly, the NAS also accepts funds from industry, another questionable procedure if results are to be unbiased. Since, however, the NAS must have funds if studies are to be done, its choices appear to be limited, and in fairness we might say that the objectivity of NAS studies has been fairly respectable, considering the constraints under which it operates. But, as Ralph

Nader has stated, its "prestigious talents are all too often subverted from working in pursuit of the public interest." [36]

Perhaps a more fundamental problem is that, admittance being honorary, the NAS membership is generally elderly (the median age of its 866 members in 1970 was 62) and therefore likely to contain a rather conservative, status-quo-oriented sample of the universe of scientists. Worse yet, many of the most talented scientists among NAS members remain immersed in their own research, leaving those with a talent for politics to exercise the academy's influence, sometimes against the public good.

Although periodically some interest is shown in "reforming" the NAS, it seems highly unlikely that any real progress will be made in that direction. Instead, other scientific organizations are gaining prominence that have open memberships, are member-supported, and are independent of government and big business; and they are beginning to give science a respected voice on social issues. Prominent among them is the Federation of

---

[33] Ibid., p. 508.

[34] For example, see John P. Holdren, "The nuclear controversy and the limitations of decision-making by experts".

[35] For a detailed critique, see P. Boffey, *The brain bank of America*. This commentary has been described as harsh by some academy members, but its fundamental validity seems indisputable to anyone who has observed the functioning of the NAS for any period.

[36] Introduction to Boffey, *The brain bank*, p. xxiii. See also Harold Green's analysis of NAS president Philip Handler's defense of DDT. The risk-benefit calculus in safety determination; and Handler's reply, A rebuttal: The need for a sufficient scientific base for government regulation.

American Scientists (FAS), which has about 7000 members (compared to the NAS 1000), including half of America's Nobel laureates. The FAS declines, rather than relies upon, government contracts, which may explain why its budget is only one five-hundredth as large as that of the NAS. But its voice is already more persuasive to many because of its independence.

Outer Space and the Environmental Crisis

Repeatedly, since it has become clear that population growth was moving humanity into an ever-worsening crisis, the suggestion has been made that *Homo sapiens* seek relief from the pressures it was generating by migrating away from Earth. That this is an unsatisfactory long-term solution follows immediately from arithmetic. Under any scenario of exponential growth at rates close to those on Earth today, everything in the visible universe would have to be converted into human flesh in a few thousand years, and a cosmic ball of people would soon thereafter be expanding with the speed of light. At a more mundane level, biologist Garrett Hardin in 1959 published some simple calculations demonstrating the utter impracticality of launching spaceships from Earth on a large enough scale to solve human population problems by interstellar migration, [37] Soon thereafter, physicist John Fremlin pointed out that, at then current growth rates, any time humanity wished to "solve" the population problem by extraterrestrial migration, it would take only about a half-century to populate Venus, Mercury, Mars, the moon, and the moons of Jupiter and Saturn to the same population density as Earth -- since the surface areas of these planets and

moons are not 3 times that of Earth, they would reach the Earth population density in less than two doubling times. [38] Recently a new and rather different approach to solving human problems in outer space has been proposed, not by science fiction writers but by a respected professor of physics, Gerard K. O'Neill of Princeton University. The basic idea is to colonize not planetary surfaces but space itself, drawing energy from the sun and materials first from the moon and then from the asteroid belt. O'Neill and his colleagues have done extensive preliminary calculations and conclude that, without the development of radically new technologies:

> 1. We *can* colonize space, and do so without robbing or harming anyone and without polluting anything.
> 2. If work is begun soon, nearly all our industrial activity could be moved away from Earth's fragile biosphere within less than a century from now.
> 3. The technical imperatives of this kind of migration of people and industry into space are likely to encourage self-sufficiency, small-scale governmental units, cultural diversity and a high degree of independence.
> 4. The ultimate size limit for the human race on the newly available frontier is at least 20,000 times its present value [about 500 years of growth at present rates]. [39]

The general plans for O'Neill Colonies have been widely discussed and need not concern us in detail here. [40] An ingenious plan has been devised for propelling materials excavated from the moon's surface to the assembly sites of the first colonies where the materials would be processed on the spot. The processing would take advantage of the abundant solar energy, convenient heat sink, and zero gravity of space. The colonies would be both self-replicating and virtually entirely selfsustaining. Oxygen, for instance, would be recovered from the lunar soil -- although hydrogen to be combined into water would be one of the few imports from Earth. The first colony might well be a space manufacturing facility (SMF) established at Lagrange 5 (L5), a point in space that follows the Earth and the moon, has zero gravity, and about which thousands of colonies could move in quasielliptical orbits.

The first products of the SMF could be huge solar power plants (Satellite Solar Powered Stations, SSPS)

which would beam low-density microwaves to Earth where they would be received by antenna arrays, converted to electricity, and fed into power lines. [41] Subsequently, colonies could be built as space habitats of what at first seem to be daunting dimensions--for instance, cylinders of up to 16 miles in length and 4 miles in diameter, as in O'Neill's earlier plans, or perhaps spheres of

similar volume, which he now thinks superior. [42] The colonies would be shielded from cosmic radiation, would receive day-length sunlight with a system of mirrors, and would rotate to produce normal gravity on their inner surfaces. Within the colony, O'Neill envisions a very pleasant environment for up to 10,000 people, including large areas of "natural" environment with trees, grass, birds, bees, butterflies, and bodies of water. A wide variety of sports and diversions would be available, enhanced by the options of pursuing them at normal gravity on the inner surface of the station or at zero gravity at the rotational axis. Industry would be carried on largely at zero gravity, which provides great benefits; [43] agriculture would be assigned to separate chambers where it could take advantage of an infinite variety of light regimes, gravities, atmospheres (including high CO_2,), and so on.

The prospect of colonizing space presented by O'Neill and his associates has had wide appeal, especially to young people who see it opening a new horizon for humanity. The possible advantages of the venture are many and not to be taken lightly. In theory, many of humanity's most environmentally destructive activities could be removed from the ecosphere entirely; the population density of the Earth could be reduced; and a high quality of life could be provided to all *Homo sapiens*. It might even make war obsolete.

What can one say on the negative side about this seeming panacea? At the moment the physical technology exists largely on paper, and cost estimates depend in part on numbers from the National Aeronautics and Space Administration (NASA)--not necessarily a dependable source. [44] There appear to us, however, to be no more technical barriers inherent in the further development of the O'Neill technology than in others in which society has committed itself to large, open-ended and highly speculative investments--fusion power technology being a prime current example, the atomic bomb one from the relatively recent past.

On the biological side, things are not so rosy. The question of atmospheric composition may prove more vexing than O'Neill imagines, and the problems of maintaining complex artificial ecosystems within the capsule -- or anywhere -- are far from solved. The microorganisms necessary for the nitrogen cycle and the diverse organisms involved in decay food chains would have to be established, as would a variety of other microorganisms necessary to the flourishing of some plants. "Unwanted" microorganisms would inevitably be included or would evolve from "desirable" ones purposely introduced. Furthermore, in many cases the appropriate desirable organisms for introduction are not even known. Whatever type of system were introduced, there would almost certainly be serious problems with its stability. Biologists simply have no idea how to create a large, stable artificial ecosystem. For a long time it is likely that the aesthetic senses of space colonists would have to be satisfied by artificial plants, perhaps supplemented with specimen trees and flower beds.

The problems in the agricultural modules might be easier to solve but are far from trivial. Since, according to O'Neill, agricultural surface is relatively cheap to construct, it seems likely that early stations should have perhaps 4 times as much as is required to sustain the colony, and that it should be rather highly compartmented and diverse to minimize the chances for a disaster to propagate. A great deal of research will have to go into developing appropriate stable agricultural systems for space. The challenge is fascinating -- especially because of the variety of climatic regimes possible, the potential for excluding many pests, and the availability of abundant energy.

We can say, then, that although there appear to be no absolute physical barriers to the implementation of the O'Neill program, potentially serious biological barriers remain to be investigated. What about psychological, social, and political barriers? The question of whether *Homo sapiens* can adapt to the proposed space station environment seems virtually answered. Six thousand

[44]For example, Les Aspin, "The space shuttle: Who needs it?"

men live for long periods on a navy supercarrier orders of magnitude smaller than a proposed space habitat, without women and without numerous amenities of life envisioned by O'Neill. Many city dwellers pass their lives in similarly circumscribed areas and in much less interesting surroundings (travel among stations and occasionally back to Earth is envisioned). There is little reason to doubt that most people would adapt to the strange situation of access to different levels of gravity. Whether or not society will support the venture is another matter. Much may depend on whether O'Neill's calculations [45] on the profitability of the solar-power generating enterprise stand up under closer scrutiny and limited experiment.

The strongest objections that will be raised against space colonization are that it cannot help humanity with the problems of the next crucial decades; that it will divert attention, funds, and expertise from needed projects on Earth; and that it is basically just one more technological circus like nuclear power or the SST. That space colonies will have no immediate impact is recognized by O'Neill, but he argues that society should look to medium-range as well as short-range solutions. Diversion of funds and expertise also do not seem to be extremely serious objections. There is, for instance, no sign that capital diverted from, say, a boondoggle like the B-1 bomber would necessarily be put to "good" use. Equally, it does not follow that money for space colonies must be diverted from desirable programs. The expertise needed is superabundant -- many trained aerospace engineers, for example, were unable to find appropriate employment in the mid-1970s.

The possibility of diverting attention from immediate problems like population control is much more serious and can only be avoided by assiduous care on the part of O'Neill and other promoters of the project. Some of O'Neill's associates have done his cause grave harm by not realizing this. At every stage people must be reminded that, for the potential of space even to be explored, a functioning society and economy must be maintained for the next three decades.

Environmentalists, including us, had a strong negative reaction to O'Neill's proposals when first presented with them. [46] The proposals smack of a vision of human beings continually striving to solve problems with more and bigger technology, always turning away from learning to live in harmony with nature and each other and forever dodging the question of What is a human being for? But, again, O'Neill's vision shares many elements with that of most environmentalists: a high-quality environment for all peoples, a relatively less populated Earth on which a vast

diversity of other organisms can thrive in an unpolluted environment with much wilderness, a wide range of options for individuals, and perhaps time to consider those philosophical questions. The price of this would, of course, be a decision that a substantial portion of humanity would no longer dwell on Earth.

Environmentalists often accuse politicians of taking too short-term a view of the human predicament. By prematurely rejecting the idea of space colonies, they could be making the same mistake.

MEDICINE

By the 1970s members of the medical profession in the United States and elsewhere were becoming aware of the seriousness of the population problem and the role that medicine has played in creating it, as well as the role that profession must play if the problem is to be solved. More and more physicians now realize that medical intervention in lowering death rates must be balanced by intervention in lowering birth rates. In the United States, courageous doctors openly defied antique abortion laws and risked grave financial loss by performing vasectomies before the legal climate became favorable to those procedures. Interest in the problems of environmental medicine has been rising also, and medical doctors have been at the forefront in sounding warnings (often ignored) about the hazards of air pollution, water pollution, and other environmental threats to public health.

On the debit side, the medical profession as a whole was tardy in backing even such elementary programs as the repeal of laws limiting sex education, the distribution of contraceptive information, and the establishment of

---

[45]Space colonies and energy supply.

[46]See, for example, *Coevolution Quarterly*, Spring 1976.

family-planning services for the poor. Furthermore, medical training has militated against abortion except under extremely limited circumstances, and the record of the profession (in contrast to those of some courageous individual physicians) in the area of abortion reform was atrocious. For some time after a so-called liberal abortion law was enacted in California, a substantial portion of the abortions in that state continued to be performed by a single group of doctors. Even two years after abortion was legalized nationwide in 1973, only 17 percent of public hospitals and a pitifully small number of private clinics offered abortion services. [47] The medical profession should have taken the lead in abolishing not only the abortion laws but all of the pseudolegal hospital rituals attendant to performing abortions.

The history of the medical profession's attitude toward voluntary sterilization in the past also has generally been reactionary and moralistic. For example, "quotas" based on a woman's age and the number of living children she had were commonly used to determine whether that woman could obtain voluntary sterilization in many United States hospitals during the 1960s. [48] The doctor has the responsibility of establishing that a patient fully understands the consequences of

sterilization and any possible temporary side effects, and that he or she would not be physically harmed by the operation. But the doctor should have no right to make the ultimate decision whether an adult should be voluntarily sterilized.

The American Medical Association is an extremely powerful organization and an enormous potential force for good. But, as in many other areas of social reform, such as in providing decent health care to all Americans, the AMA has conspicuously dragged its feet on the population controversy. Rather than leading the crusade for population-control measures, particularly those that pertain to medical practice, the AMA finally went on record as supporting these policies only after pressure was applied from outside by the public and from within by the younger members.

Whether the medical profession in the United States will become a strong force for population control remains to be seen. It has a great potential for helping to solve the population problem, both at home and through technical aid to other countries. Many medical professionals in the United States, for instance, have actively assisted in training programs for understaffed familyplanning and general public-health services in less developed countries. Such activities could be expanded and encouraged within the profession.

In addition, the medical profession can be taken to task for concentrating far too little effort on "health care" and far too much on "disease care." Again with outstanding exceptions among individual physicians, organized medicine has, for example, failed to take any lead in questioning the public-health consequences of the largescale technologies used in agriculture, power generation, transportation, and other sectors of modern life. While medical and biological scientists have wasted billions of dollars in ill-conceived searches for cancer cures, the AMA has been largely silent about the environmental causes of the vast majority of cancers (see Chapter 10). It is high time that the medical profession as a whole threw its enormous prestige into the battle against environmental deterioration, particularly those aspects that threaten public health.

Finally, we must note that the entire pattern of modern health care has been strongly attacked by that prince of intellectual iconoclasts, Ivan Illich. Illich claimed that modern medicine is destroying our health, turning us into "slaves of a monopolist international medical industry" -- consumers of a product called health. [49] As with Illich's devastating critique of education (see *"Education"*), his opinions deserve careful attention even if they are extremely heterodox, and even if his suggestions for change seem impractically individualistic. [50]

EDUCATION

In the United States and around the world there clearly has been an almost total failure to prepare people to understand and make decisions relating to the populationresource-environment crisis. The universities, which

should be leading the way in education, have been too conservative and too compartmentalized. Unfortunately, most human problems do not fall neatly into such academic categories as sociology, history, economics, demography, psychology, or biology. The solutions to these problems require the simultaneous application of the best ideas from many academic disciplines. The failure to provide a multidisciplinary education partially explains the optimism of many physical scientists, economists, technologists, and others relative to the environmental crisis. Their kind of optimism is exemplified by a statement by physicist Gerald Feinberg, who wrote in 1968, "Most of our immediate problems will be solved in a relatively short time by the march of technology and the worldwide spread of those aspects of Western culture that are responsible for our high living standards." [51]

Consequences of Overspecialization

There are many examples of such naive optimism mixed with cultural chauvinism that testify to the failure of schools to provide a broad appreciation of science and technology and to place them in a sociopolitical context. The illusion that the Green Revolution would save humanity from starvation, common in the early 1970s, illustrated a faith in science and technology characteristic of the "well-informed" layman. That faith is all too often shared by academicians who have acquired little insight into biology and into what is involved in raising crop yields or in establishing agricultural development in poor countries. Ignorance of the environmental consequences of population expansion leads many social scientists to underrate the significance of population growth in the DCs and the immediacy of the environmental threat.

Such narrowness of outlook is not exclusive to any particular group of scientists. For example, an oceanographer, ridiculing some of the ecological problems associated with agriculture, once told an audience at the University of California at Berkeley that, with modern fertilizing techniques, soil only serves to prop plants up. The president of the United States National Academy of Sciences, writing in the journal *Science*, at various times has attacked scientists who were trying to have DDT banned and has downplayed the health effects of air pollution and the probable overall impact of nuclear war. Many of the solutions put forth by technological optimists are based on ignorance of ecology, demography, anthropology, sociology, and other nontechnological fields. Those who see a panacea in nuclear agroindustrial complexes, for instance, are simultaneously required to ignore (among other things) economics, the scale of the food problem, the state of reactor technology, the potential ecological damage, and an entire spectrum of political and social complexities. Those few technologists who still propose migration (to Australia or to other planets) as a solution to the population problem, or who would accommodate surplus people in concrete cities floated on the sea, simply need remedial work in arithmetic. Even projects that *might* be technically feasible can provide no amelioration of the dilemmas of the near future, because *rate problems* guarantee too great a lag-time.

When highly trained and presumably knowledgeable people are so uninformed, it is hardly surprising that the average person has difficulty evaluating the situation. Not only do most citizens of the United States and other developed countries lack even a skeleton of the necessary technical background, but many do not feel confident enough of their analytic abilities to do even the elementary "back-of-the-envelope" calculations that might permit them to decide which of two "experts" is correct on a given question. For instance, exposing as fraudulent the notion that the Alaskan oil field would be a panacea for American energy needs would require only dividing U.S. annual consumption of oil (6 billion bbl) into known and estimated Alaskan reserves (9 billion and 45 billion bbl, respectively). Unfortunately, few people think of making such checks for themselves. Those who might, often would not know where to find the information on comsumption and reserves--high schools and universities turn out few students well versed in the use of libraries.

The fast-approaching problems of the future will require a citizenry equipped to make difficult choices and to evaluate the qualities of leaders, whether in politics or business. Too few graduates of any educational level (high school to Ph.D.) today have the broad backgrounds

[51]Quoted in Ehrlich and Ehrlich, *Population, resources, environment*, p. 357.

necessary to make such choices intelligently. Too few citizens understand the workings of the political and economic systems well enough to begin making appropriate changes in those systems--such lessons are not taught in school.

New Priorities for Education

The goals of the educational system in the United States need to be reexamined, and new priorities need to be set. At present, the system is largely failing to meet even the old stated goals. But such an overhaul of the educational system will require the cooperation of some elements of society who may see in it a threat to their own interests--from the small group of the ultra-rich, who control much of the power in the United States and who want no changes in the system, to entrenched university professors whose doctrinaire defense of rigid boundaries between their separate disciplines is one more obstacle to solving the world's problems.

One would think that many of the needed educational reforms could be introduced relatively easily at the university level. Unfortunately, like all other mature institutions, universities are quite resistant to changes in their antiquated structures. Nevertheless, the possibility does exist of loosening the rigid departmental organization in order to provide some exchange of information and ideas among disciplines, even though the rate of movement is still very slow. Stanford University, with the help of the Ford Foundation in 1970, developed an interdisciplinary undergraduate curriculum in "Human Biology," with the express purposes of avoiding the trap of disciplinary myopia and of preparing students to engage pressing human problems. By 1975 the program included 350 undergraduate students and was the third most popular major on campus. In 1973, the University of California at Berkeley instituted a campuswide interdisciplinary

graduate program in Energy and Resources, which now has tenured faculty not assigned to any department--a significant break with tradition.

Many other colleges and universities have also instituted interdisciplinary programs of various sorts, while courses dealing with the problems of the survival of civilization are proliferating on lower educational levels as well. Such reforms, however, must continue to accelerate if the educational system is to contribute in any significant degree to improving civilization's chances. Without a growing cadre of well-educated people, the kinds of citizen-participation programs we suggest later in this chapter will not constitute much of an improvement over the present political system.

The Role of Students

Perhaps the greatest hope for action in our universities and colleges lies with the students. Although the activism of the late 1960s has faded, students in the mid-1970s as a group are still much more socially aware than were the students of the 1950s and early 1960s. Many seem determined to change our society for the better and are actively working for political and social change. In our opinion and that of many colleagues, the majority of the most exciting and progressive changes in higher education during the 1960s had their roots in student activism. We hope that those former students, who are now beginning to take responsible roles in business and the professions, may in the 1970s and 1980s produce equally salutary changes in other institutions as well.

To a large extent, recent college graduates and students today have more realistic views of the world than their parents because they do not see it through the rose-colored glasses that were constructed for earlier generations by society and its educational system. Those who matured just before World War II were young during a time when personal financial insecurity was an overriding consideration for much of the population. Since World War II, students have grown up in an era when, for most, financial security could be taken for granted, so other social issues could claim their attention. The period was also one of unprecedented change. The world was brought into students' homes through the medium of television, and they were forced into a global outlook by global threats to their personal safety. Many of these young people are change-oriented and concerned about other people, and they think about subtle problems that involve all of humanity. That they show such concern should not be viewed as anything but a hopeful sign.

Although the educational system below the college level is in some ways less resistant to change than colleges and universities, it is similarly inadequate in preparing people for the realities of the world crisis. In some of the better school systems, however, there have been changes--sometimes at the initiative of students. Elementary and junior high school students in many areas have in various ways demonstrated their concern about environmental deterioration. Many teachers have encouraged interest in population growth and the environment, with or without administrative support. Since Earth Day 1970, in particular, there has been a widespread effort to introduce environmental concern into schools at virtually every level. Programs to encourage

environmental and population education in schools have also been established at the federal level in the Department of Health, Education and Welfare.

Sex Education

A lack of adequate sex education is still a serious problem in the United States and many other countries. We face both a population problem and a venereal disease epidemic in the United States, and yet powerful groups are determined to keep the "facts of life" from our young people. No subject is more likely to bring out a mob of angry parents than the thought of introducing the most innocuous sex-education curriculum into a school, even if the program is endorsed by educators, psychiatrists, and clerics of many faiths. Some parents in our sex-saturated society even claim that a straight-foward description of sexual intercourse, of the sort that should be perfectly acceptable reading for any child, is part of a communist plot to destroy our youth! This is a vicious cycle, with a minority of ignorant or disturbed parents fighting to guarantee that their children grow up equally ignorant or disturbed.

There are, of course, formidable barriers to reasonable sex education in schools, churches, and in the home. One is a lack of training for potential teachers, who must have a thorough understanding of the subject. The second is the nearly ubiquitous feeling that sex education must be tied up with moral judgments. In the face of massive ignorance and our current population crisis, however, it is difficult to construct an argument against teaching about three basic aspects of sex in the schools. First, children must be thoroughly informed about the anatomy of sex organs and the physiology of sex and reproduction. Second, they must be taught the difference between "sex" and reproduction and about the methods of contraception. Third, they should be informed of the dangers of venereal disease.

These straightforward factual matters are easy. Introducing the student to the role sex plays in society, the attitudes toward it in different religious and social groups, attitudes toward contraception, illegitimacy, marriage, divorce, virginity, and sex-as-just-plain-fun must be handled with great care and by specially trained teachers. But the cycle of the blind leading the blind, that of embarrassed and uninformed parents "educating" their children, must be broken somehow. The experience of Planned Parenthood and other organizations that help teenagers with sexual problems (often unwanted pregnancies) is that keeping youngsters ignorant does not prevent early experimentation with sex, as is usually the intention. On the contrary, informed youngsters seem much less likely to engage in sexual adventures before they are emotionally ready and are even less likely to find themselves incipient parents.

One way in which school systems have successfully introduced sex-education programs is by giving parents a preview of the material. The parents are invited to evaluate the program--in fact, one purpose is to educate *them*. Such preparation of the adult population would seem essential to avoid perpetuating ignorance. A sexeducation program has even been initiated in West Germany for grandparents, who often care for children while parents work. Perhaps sex education should be promoted for all parents of preschool children in the United States.

In recent years, at least, several frank and competent books have become available for those interested enough to educate themselves. For preadolescents, the book *Where did I come from?*

by Peter Mayle is excellent, and for young women, *Our bodies, ourselves* by the Boston Women's Health Book Collective has produced a revolution of understanding. At a more comprehensive and intellectual level, we can recommend *Fundamentals of human sexuality* by psychiatrists Herant Katchadourian

and Donald Lunde, which has enjoyed great success as a college text and is highly recommended for any adolescent or adult who wants to understand his or her sexuality.

The Brain Drain

Our educational system is failing to produce not only those competent to teach sex education, but also the ecologists, agricultural scientists and technicians, social scientists, paramedical personnel, and various other specialists needed to help solve the pressing problems of the world--especially in the less developed countries. Indeed, for decades there has been a brain drain. Trained personnel from the LDCS, especially medical doctors, are understandably attracted to the United States and other DCs, where they can earn a good living. Ironically, this often happens because, despite their great needs for trained people, LDCs may have no jobs for them. That many individuals from the LDCs who are educated in the DCs do not wish to return to their homelands is even sadder. Although some DCs, notably the Soviet Union, virtually force a return to the homeland, most do not. One relatively simple and humane solution would be for the DCs to establish and help staff more training centers *within* the LDCS. This should have the additional benefits of training local people to work on problems of local significance and of familiarizing visiting faculty members from the DCs with those problems.

Changing the Educational Structure

While a great deal can be done to improve the educational system within the general framework now recognized, more fundamental changes will probably be required if large technological societies are to discover ways to govern themselves satisfactorily while solving or preventing the social and environmental problems that now threaten to destroy them. Ivan Illich has suggested the abolition of formal education and the making of educational materials and institutions available to all on a cafeteria basis. [52] To those struggling in the present system, the idea has considerable appeal; but even Illich recognizes the enormous drawbacks inherent in such an unstructured approach.

We would suggest another strategy, one that expands on ideas already current in education. First of all, we think that a major effort should be made to extend education throughout the life span, rather than attempting to cram all education into the first fifteen to twentyfive years. It is becoming widely recognized that maturity and experience are often a benefit in learning. Students who have dropped out, worked, and then returned to school generally do so with renewed vigor and increased performance. Experience in the real world can lead students to avoid much wasted effort in the educational world. A program of encouraging interruption of education, perhaps for one or two years during or directly after high school and another two years after receiving an undergraduate degree might be a good start. For example, a student

interested in becoming a physician might spend two years after high school doing clerical work in a hospital or doctor's office or serving as an orderly. When his or her undergraduate education was completed, two additional years could be spent working with a doctor as a paramedic. Similarly, individuals going into business, government, science, bricklaying, plumbing, or whathave-you should have a chance to try out their chosen professions and trades at the bottom before completing their educations. [53]

The benefits of the program would be many, including better understanding of the problems faced by associates (a doctor who has been an orderly should have more insight into the situation of the orderlies), and fewer cases of people committing themselves to careers too early, with too little knowledge of what the commitment involves, and discovering the error too late to make another choice. Students who, on completing high school, were unsure of what their futures should be, could try out several possibilities.

What about youngsters who have no desire to go beyond high school or vocational school? Should their educations end at that point? In the United States, for instance, nearly 1 adult in 5 reportedly lacks "those skills and knowledges which are requisite to adult compe-

[52] *Deschooling society*.

[53] For a more detailed discussion of restructuring our educational system, see Dennis C. Pirages and Paul R. Ehrlich, *Ark II: Social response to environmental imperatives*, chapter 6.

tence." [54] We believe that a technological society, especially a democracy, cannot afford such a large proportion of poorly educated citizens.

Every citizen should be drawn into the problems of societal decision-making. We would suggest that *all* people be required to take sabbatical leaves every seventh year, which could be financed in various ways depending on the choice of activity (this and the employment "problems" created by such a program are considered under "Economic and Political Change"). Each person would be required to spend the year bettering society and himself or herself in a way *approved by the individual's immediate colleagues*. A physician might petition his or her county medical society for permission to study new surgical techniques or anthropology. A garbage collector might petition coworkers to permit him or her to take a year's course in sanitary engineering or recycling techniques at a university. A secretary might apply to the government for a grant to spend a sabbatical serving on an ad hoc citizens' committee to evaluate the direction of research in high-energy physics. A business executive might apply for one of the open sabbatical chairs that could be established on the city council (as well as in all other legislative bodies). A flight instructor might persuade the local pilot's association to appoint him or her to one of the exchange positions in the local Federal Aviation Administration office, with an FAA counterpart being required (if qualified) to take over the instructor's job for a year. *All* bureaucrats should be required to take some of their sabbaticals as nongovernmental workers in the areas they administer and all professors to take some of theirs outside the groves of academe--or at least outside their own fields.

The details of such a program would be complicated, but its benefits, we believe, would far outweigh its costs. A growing rigidity of roles in our society must be broken, and virtually everyone must be brought into its decision-making processes. Indeed, the discontent expressed today by many groups is based on their feeling of being cut off from participation in important decisions that affect their lives.

Some moves in this general direction have been made in the People's Republic of China, where city people and academics have been forced to join rural communes and participate in completely different work from what they had done before. It would be interesting to know what success the Chinese have had. We would certainly not advocate forcing people to change their occupations against their wishes, any more than we would advocate adopting the Chinese communist system of government. But the basic idea behind this policy seems valuable, and an adaptation of it that fit our political system might well be worth exploring.

As an example of how citizen participation in political decision-making can work, a group of scientists led by ecologist C. S. Holling at the University of British Columbia have involved local businessmen, politicians, and private citizens in a computer simulation of a prospective development project, as an experiment in the results of citizen decision-making. [55] Everyone contributed to the assumptions of the model, and all were satisfied with the model created. Then various people were allowed to try out their pet development plans on the model. When a politician found that his or her plan led to environmental disaster, the politician had to acknowledge the error. The politician could not blame the model because he or she had been involved in building what was believed to be a realistic one.

We believe that it is possible, at least in theory, to get away from a we-they system of running the country, to give everyone a chance to participate. Grave problems would unquestionably accompany the attempt, but since we are both morally committed to some form of democracy and intellectually convinced that the present system is both undemocratic and lethally ineffectual, we see no choice but to try a change.

THE LEGAL SYSTEM

Perhaps the greatest potential for reversing environmental deterioration in the United States and for bringing our population growth under control lies in the effective utilization of our legal system. [56] A law may be defined as

---

[54] Based on a U.S. Office of Education study, reported in *Time*, November 10, 1975, p. 6.

[55] Personal communication.

[56] Much of this section is based on discussions with attorney Johnson C. Montgomery, whose death in December 1974 was a loss deeply felt by people in the ZPG movement.

a "rule of conduct for a community, prescribed by a governing authority and enforced by sanction." The sanction enforcing a law may be either a reward or a punishment. For instance, to control agricultural production, the government might pay a subsidy for not raising crops on part

of his land (a reward) or jail a farmer who raises crops (a punishment). Where a government wishes to induce an affirmative action, a promised reward is often more effective than the threat of punishment. In the United States, constitutional questions involving due process, equal protection, and so forth are more likely to arise where punishment, rather than reward, is involved. Bonuses for not having children would certainly raise fewer constitutional questions than jail for overreproducers, for example.

Law is also sometimes defined as codified custom. In a sense, legislators, police officers, and judges are merely social instruments for enforcing customary behavior. Historically they have also helped to create custom by defining acceptable conduct. This has been especially true of legislators and is becoming increasingly true of judges. When the new problems of local and global overpopulation and environmental deterioration arose, they clearly demanded the establishment of new rules of conduct and new customs--in short, new laws. Just as the ancient laws relating to trespass had to be modified by the courts and by the legislatures to handle the new circumstances created by automobiles and airplanes, new devices are now being developed for dealing with pollution and population pressure. The laws of the free-enterprise system were failing to meet the needs of everyone everywhere as long as they permitted--let alone encouraged--unrestricted reproduction and pollution.

Environmental Law and Lawsuits

Many aspects of environmental deterioration can be curbed or controlled through legal means. Probably the easiest form to control is pollution, whether caused by industry in the processes of mining and manufacturing or by individuals in their ordinary lives (air pollution from automobiles and home heating, for instance). Before 1965, there was relatively little control by law of pollution, and the existing regulatory mechanisms were quickly becoming obsolete and inadequate as the volume and variety of pollutants multiplied. Fortunately, there are many legal precedents that have permitted society to oppose polluters legally. Two examples are the legal precepts of *nuisance* and *trespass*.

Nuisance. Under common law (the law generally applicable in the United Kingdom and former British colonies) and under civil law (the law generally applicable in the rest of the Western world), the concept of nuisance has for centuries permitted governments to bring some of their coercive powers to bear on those who create excessive smoke, noise, odor, filth, and the like. In some jurisdictions access to sunlight and even an attractive view are among the aesthetic values protected by public administrators. Public administrators, however, in general have not been noted for their diligence in complaining about local businesses. Nuisances have more often been successfully stopped by individual citizens who have obtained injunctions to stop them. (Private citizens may receive money damages for injuries caused them by a nuisance.)

Existing nuisance laws have presented a number of difficulties, however. First, the nuisance doctrine generally serves only to protect rights associated with real property. As matters now stand, a private nuisance can be stopped only by a person occupying adjacent or nearby property. Even in the most enlightened jurisdictions, little if anything can be done to protect people in the vicinity who do not own or occupy property.

Second, the nuisance doctrine requires that a complainant show a causal relationship between the condition he or she is complaining about--for example, smoke or noise--and a direct injury to himself. Generally he has to show that the condition is *the* cause of injury. Obviously, if each of several polluters contributes a little to the overall problem, the nuisance doctrine is not much help. On the other hand, there is growing authority for the proposition that if a suit is filed against all the persons who are contributing to a nuisance, it is up to them to show to what extent each has contributed. Thus there have been successful cases involving river pollution in which *all* upstream contributors have been sued.

Third, the nuisance doctrine is applied only if in the eyes of the court the polluter is causing more harm than

good. Unfortunately, it has been held by many courts that a so-called lawful business (paint manufacturing, for example) cannot constitute a nuisance. Today there is an increasing public tendency to recognize the dangers from pollution, however, and, in balancing them against economic considerations, to require businesses to do whatever a court or an administrative agency may think is economically reasonable. For instance, in the case of *Boomer versus Atlantic Cement Company*, [57] individual plaintiffs were awarded damages for cement dust falling on their property, but the court refused to issue an injunction that would halt the plant's operations, even though it found those operations created a nuisance. The court reasoned that the economic activities of the company were too valuable to the area and too many other people would be harmed if the plant were closed down.

That the economic interests of the polluters are taken into consideration by government authorities, however, often leads to spurious arguments based on the notion that restrictions would foster unfair competition: "We can't compete with the Jones Company if we can't spray our crops with DDT." The answer to this argument of course is: "We will stop the Jones Company too." Often the best way of avoiding unfair-competition arguments is to pass legislation that affects an entire industry. For example, if a law were passed prohibiting the manufacture of *all* persistent insecticides (for instance, all those with half-lives of more than one week under average field conditions), the chemical companies would very quickly increase production of those that met the requirements and would develop new ones that would also break down rapidly.

The serious defects in the existing nuisance laws might make it appear that they cannot really assist in controlling pollution, but that is not so. With relatively minor adjustments, those laws could be made very effective. These are among the changes that must be made: (1) expand the nuisance doctrine to include people who are hurt by the pollution but who do not occupy nearby property; (2) permit individuals to bring actions not only on their own behalf, but also on behalf of all other individuals in similar circumstances who are being damaged by pollution; (3) permit recovery of punitive damages (damages in excess of the dollar value of the injury suffered) in cases where the polluter could have avoided some or all of the pollution; (4) organize public-spirited scientists so that they might become a more readily available source of testimony. The real value of the nuisance laws is that they provide an existing framework within which to

elaborate newer and more restrictive rules of conduct without also requiring the development of previously unrecognized rights and duties.

Trespass. Another ancient legal doctrine, that of trespass, can also assist in stopping pollution. According to law, if you hit another person with your fist or with your automobile, or if you hike over another person's land, you have committed a trespass. Trespass is both a crime (a public offense) and a tort (an individual, private injury).

For many years there have been metaphysical arguments concerning what constitutes a trespass--for example, whether it is necessary to be able to see whatever hits you or falls on your land. It has been said that rays of light cannot constitute a trespass, and in the past not even smoke could constitute a trespass. However, the old idea that it was necessary to be able to see, feel, and even weigh the offensive object is going out of style. The decision in one California case permitted recovery of substantial damages for lung injuries sustained by a motorist who drove through invisible chemical fumes emitted by a factory.

One serious defect in applying the trespass laws to the control of pollution is that the most an individual can recover are the damages to that individual, which are generally limited to the monetary value of the private injuries. In one case, however, the Oregon Supreme Court permitted a private individual to collect punitive damages in addition to his actual personal damages. The court reasoned that some private wrongs are so evil that the wrongdoer should be punished as well as being forced to pay for the actual injury to the complainant. Punitive damages have long been recognized in our legal systems. If industries guilty of pollution are assessed for punitive damages, private individuals will have some incentive to initiate lawsuits against them. Recently, this possibility has induced some industries to curtail their

[57]1970. 26 N.Y. 2d 219, 257 N.E. 2d 870, 309 N.Y.S. 2d 312.

pollution. It has also induced some insurance companies to withdraw insurance against such suits, and a few states have contemplated the prohibition of insurance for pollution liability.

Like nuisance laws, the trespass laws could be made much more effective merely by permitting an individual to sue for the value of the injuries sustained by *all* individuals similarly situated. Such suits are called *class actions*, and the individual represents not only himself or herself, but also all others similarly situated or in the same class. There exists ample authority for class actions in other circumstances. For example, a stockholder has long been able to bring a class action on behalf of all stockholders against a corporation or its officers or directors. Today, there is evidence that trespass laws will increasingly be used in what are essentially class actions against polluters. The suits against the Union Oil Company by the State of California and by individuals in connection with the 1969 oil leak in the Santa Barbara Channel were class actions. In 1973, however, the class-action approach to legal intervention to improve environmental quality received a setback. The United States Supreme Court declared that each member of a class must suffer damages of more than $10,000 (rather than pooled damages amounting to that much) before a federal court could hear an environmental lawsuit. [58] Since such individual

damage is rarely demonstrable, environmental class actions successfully prosecuted in federal courts will become relatively rare.

Suits and interventions by public-interest groups. Perhaps the most impressive success story in the legal battle for the environment has been the rising influence of a relatively few organized public-interest groups that have been using the lawsuit and other forms of legal intervention in a persistent and systematic way. A pioneer in this respect has been the Environmental Defense Fund (EDF). This organization, composed of scientists, lawyers, and other citizens, has been going into the courts and appearing before government regulatory agencies since the late 1960s in its efforts to protect the environment. It started in 1966 by using the courts to stop spraying with DDT in Suffolk County, Long Island. As a result of the publicity accompanying the EDF suit, the state of Michigan rigidly restricted the use of DDT. Then, in an adversary-style hearing before the Wisconsin Department of Resources between December 1965 and May 1969, EDF was able to demolish the flimsy case of those attempting to defend continued use of DDT. [59] Faced with the certainty of cross-examination, many of the scientists who usually defended the petrochemical industry were noticeably absent from the witness chair (although not from the public press).

As a result of those hearings, DDT was banned in Wisconsin. EDF then carried its battle to the federal level, where it played a major role in persuading the Environmental Protection Agency to declare a virtually complete ban on use of DDT in the United States at the end of 1972 (see below). [60] Originally a shoestring operation, EDF has gained considerable admiration and support from scientists and others aware of such environmental threats. Other groups, such as the Natural Resources Defense Council (NRDC, founded in 1970), have also become very active in taking environmental issues to court. In 1975 NRDC had a staff of four scientists and fourteen attorneys, and had on its docket more than 100 lawsuits and other legal actions of national significance. Environmental groups like Friends of the Earth and the Sierra Club have also been involved, alone or in coalition with other groups, in many such actions in defense of the environment, frequently in cooperation with the legal staffs of EDF or NRDC. Some of the most notable accomplishments of the legal actions undertaken by the growing and increasingly sophisticated collection of environmental public-interest groups are discussed in the sections that follow.

Legislation and Administrative Agencies

Both the need for and the effectiveness of legal action by individuals and citizen groups are linked to the larger

[58] *Zahn versus International Paper Company*, 414 U.S. 291 (1973).

[59] The story of the EDF at Madison is told in a very lively fashion by H. Henkin , M. Merta, and J. Staples, *The environment, the establishment, and the law*.

[60] The ban was lifted in 1974 so that DDT could be used against the tussock moth in the Northwest, a very unfortunate decision. See Robert F. Harwood , *Economics, esthetics, environment, and entomologists: The tussock moth dilemma*.

framework of existing laws and the agencies that administer them. In some sense the easiest route to improvements in environmental protection would seem to be the passage of more comprehensive controls and the establishment of streamlined procedures for administering them. Almost certainly, the courts would have no constitutional objections to any reasonable legislative limitations on the activities of polluting industries--for example, requirements that effluents be purified, reduced, or eliminated. The courts could even sustain statutes that would put certain corporations out of business.

There are two major difficulties in getting effective legislative action. First is the notion that if a higher government authority (for example, the United States Congress) enacts a law regulating a certain activity, it may have preempted the field so that a lesser government authority (for example, a state) cannot enact legislation dealing with the same subject. This has led the tobacco and automobile industries to push for federal regulation in order to avoid the enactment of possibly morerestrictive state laws. Inconsistencies in laws of different jurisdictions create a problem for industry, and there is no easy answer. A national economy does require national standards; it would be extremely difficult for the automobile manufacturers to satisfy fifty different statutory schemes to regulate automobile pollution. Yet some local problems are so severe that they require more drastic solutions than need be applied to the country at large. Thus California (and only California) is permitted tougher automobile emission standards than those established by the Environmental Protection Agency for the rest of the nation.

The second difficulty with legislative action is that legislators are often not cognizant of new problems, and some are notoriously at the beck and call of established pressure groups, such as the automobile manufacturers and the oil industry. Furthermore, in those situations where a legislature has taken action, the action has generally consisted of setting up regulatory agencies like the Food and Drug Administration, the Federal Trade Commission, or the Federal Communications Commission. Such agencies in time have tended to become dominated by the industries they are intended to regulate--ultimately the foxes wind up minding the chickens. [61] Nevertheless, as public pressure has grown, the public has already seen and can expect to see more results from legislation and from regulatory agencies than it has in the past.

In the early 1970s steps were taken in the United States toward placing stricter controls on the release of pollutants into air and water. The *Clean Air Act* (as amended in 1970) and the *Federal Water Pollution Control Act* amendments (1972) set national pollution standards for air and water. [62] As we discussed in Chapter 11, however, it was clear by the mid-1970s that the high expectations of environmentalists were not to be realized--at least not as rapidly as they had hoped. There remains a need for establishing and implementing a nationwide (to say nothing of worldwide) program drastically limiting emissions of harmful materials from industry, automobiles, homes, and other sources.

National Environmental Policy Act. A major landmark in the fight for environmental quality in the United States was the passage of the National Environmental Policy Act (familiarly known as NEPA) [63], which became law on January 1, 1970. The bill was modeled in large part after the *Employment Act of 1946*, which "declared a responsibility in the Federal Government to maintain a prosperous and stable national economy." [64] In a similar vein, NEPA declared a responsibility in the federal government to restore and maintain environmental quality.

NEPA created in the Executive Office of the President a three-member Council on Environmental Quality (CEQ), which was charged with assisting and advising the president in the preparation of the annual *Environmental Quality Report* and with carrying out a number of other survey and advisory capacities for monitoring the quality of the environment and the influence of government agencies and actions on it.

[64]Council on Environmental Quality, *Environmental Quality*, 1972, p.222.

The key provision of NEPA, however, is its famous Section 102(C):The Congress authorizes and directs that, to the fullest extent possible: (1) the policies, regulations, and public laws of the United States shall be interpreted and administered in accordance with the policies set forth in this act and (2) all agencies of the Federal Government shall --(C) Include in every recommendation or report on proposals for legislation and other major Federal actions significantly affecting the quality of the human environment, a detailed statement by the responsible official on--

i. (i) The environmental impact of the proposed action,
ii. (ii) Any adverse environmental effects which cannot be avoided should the proposal be implemented,
iii. (iii) Alternatives to the proposed action,
iv. (iv) The relationship between local short-term uses of man's environment and on the maintenance and enhancement of long-term productivity, and
v. (v) Any irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented. Prior to making any detailed statement, the responsible Federal official shall consult with and obtain comments of any Federal agency which has jurisdiction by law or special expertise with respect to any environmental impact involved. Copies of such statement and the comments and views of the appropriate Federal, State, and local agencies, which are authorized to develop and enforce environmental standards, shall be made available to the President, the Council on Environmental Quality and to the public as provided by section 552 of title 5, United States Code, and shall accompany the proposal through the existing agency review processes.

This is the section of NEPA that established the Environmental Impact Statement (EIS), which provided a crucial legal lever for public intervention on the side of the environment. The vast majority of environmental suits have been in the area of public law (concerning the relationship of citizens to the government) in contrast to private law (which deals with the relationship of citizens with one another). An early instance was the famous Storm King case, [65] a lawsuit brought by an environmental group against the Federal Power Commission, which had granted Consolidated Edison of New York a permit to build a pumped-storage hydroelectric plant below scenic Storm King Mountain on the Hudson River. The 1965 decision in the Storm King case

helped establish the standing (a position from which to assert legal rights or duties) of individuals or groups with records of concern for the environment--in other words, it established that environmentalists could sue to protect environmental values from the adverse effects of administrative decisions.

That legal step forward was followed by a half-step back in another public law case (the Mineral King case), in which the Sierra Club sued to prevent Walt Disney Productions from turning a lovely part of the Sierra Nevada into a plastic wonderland. [66] In the Mineral King case, the United States Supreme Court held that members of the Sierra Club had to use the area in question in order to gain standing; the interest of the club members in preserving the wilderness was not sufficient cause to stop the Disney project. (For a novel approach to the question of standing--an approach that would have served the environment well in the Mineral King case - see Box 14-2.)

In the context of concerned groups having standing in environmental cases, NEPA's requirement of environmental impact statements (and the required public airing of the EIS) has proven to be a godsend. A series of cases brought by groups such as the Committee for Nuclear Responsibility, the Environmental Defense Fund, the Sierra Club, and the Natural Resources Defense Council have determined that an EIS is to provide "full disclosure" of the environmental implications of any impending decision, that it must set forth opposing views on significant environmental issues raised by the proposal, that it must contain a full analysis of costs and impacts of alternatives, and that it must balance adverse environ-

BOX 14-2 A Note on Standing

The legal machinery and the basic legal notions needed to control pollution are already in existence. Slight changes in the legal notions and diligent application of the legal machinery are all that are necessary to induce a great reduction in pollution in the United States. One change in those notions that would have a most salubrious effect on the quality of the environment has been proposed by law professor Christopher D. Stone in his celebrated monograph, *Should trees have Standing?* [*] In that tightly reasoned essay, Stone points out the obvious advantages of giving natural objects standing, just as such inanimate objects as corporations, trusts, and ships are now held to have legal rights and duties. If this were done, questions such as that of the standing of the Sierra Club in the Mineral King case, mentioned earlier, would disappear -- for, as Justice William O. Douglas pointed out in his dissenting opinion in that case, *Sierra Club versus Morton* would "be more properly labeled as *Mineral King v. Morton*."

mental effects against the benefits of the proposal. [67] Failure to conform fully to the requirements has been the basis of numerous successful lawsuits in which projects have been stopped until proper environmental impact statements were prepared.

The strength of NEPA lies in the formal commitment of the government to environmental quality and the required public airing of potential impacts by the EIS procedures. In the five years 1970 through 1974, more than 6000 impact statements were filed. In the opinion of the CEQ, by 1974 NEPA had "succeeded in its objective of incorporating an environmental perspective into the decision-making process of Federal agencies." [68] This statement seems accurate to us, both because it agrees with our impressions and because, when it was made, Russell W. Peterson, one of the brightest and most straightforward of Washington bureaucrats, was chairman of the CEQ. [68a] In addition, the general approach of NEPA has been adopted by local and state governments. By 1974 twenty-one states and Puerto Rico had adopted the EIS process, as had governments in such nations as Australia, Canada, and Israel. [69] One of the most impressive of the state acts is California's 1970 Environmental Quality Act (amended), which requires impact statements on all projects, private or government, that will significantly affect the environment. In the mid-1970s some 6000 statements were being filed annually. [70]

As far-reaching and successful as NEPA has been in this context, some weaknesses are also evident. While it has raised consciousness of the environment in government agencies and in the business community, concrete results in terms of prevention and repair of environmental deterioration have been less apparent. Thus far, NEPA has been mainly an instrument for disseminating information rather than one for guiding policy. It cannot, in itself, lead to the cancellation of a project -- even though citizens groups have repeatedly employed it to delay projects where EIS provisions have not been meticulously followed. Indeed, a key flaw in the act as first applied was that its enforcement depended entirely upon the public, and the public could use it only to delay, not to halt, projects that would have massive negative impacts on the environment. [71] As far as NEPA was concerned, the Army Corps of Engineers legally could plow the United States under, or the Nuclear Regulatory Commission could permit the country to be totally contaminated with lethal amounts of radioactive wastes, as long as the EIS requirements of the law were followed scrupulously. In applying NEPA, the courts seem to be moving toward substantive rather than procedural re-

controlling economic growth. The appendix to the article contains an informative critique of NEPA.

view, however. This means that projects may be halted for reasons other than failure to follow the EIS provision meticulously. [72]

Several landmark court cases have clarified the obligations of government agencies under NEPA. In *Calvert Cliff's coordinating committee versus AEC* (1971), the United States Court of Appeals for the District of Columbia held that the Atomic Energy Commission could not exclude water quality considerations from its environmental impact statement merely because the power plant in question had already received a certificate of compliance with federal water quality regulations from the state. The court found that the "crabbed interpretation" of NEPA by the AEC would prevent the AEC from making a balanced determination of the best course of action. In *Scientists' Institute for Public Information versus AEC* (1973), the District of Columbia Court of Appeals ruled in connection with the liquid metal fast breeder reactor (LMFBR) that comprehensive environmental impact statements must be prepared for acknowledged programs, not merely for individual facilities; that is, the combined impact of many LMFBRs and the associated facilities had to be examined in advance since the AEC had acknowledged that it had a program and not a single facility in mind. In *Sierra Club versus Morton* (1974), involving fossil-fuel development on the Great Plains, the District of Columbia Court of Appeals defined requirements for a programmatic environmental impact statement in certain circumstances even where an agency had not recognized its actions as a program.

NEPA was one important step in the right direction, and it may become a prime weapon in the fight for environmental quality. But it will prove inadequate unless ways are found to introduce comprehensive environmental planning throughout the nation, in which legal standards for balancing environmental values against other values are applied to all projects with significant impact, government or private. How this might be accomplished -- and some existing legislation is leading in this direction -- is discussed further in "Economics and Political Change." That section also discusses the possibility that relatively simple legislation dealing with the consumption of resources might eventually replace much of the cumbersome ad hoc system that is now evolving for the control of environmental impact.

Environmental Protection Agency. Contrary to a rather widespread misimpression, the Environmental Protection Agency was not created by NEPA but rather by an administrative reorganization that took place in December 1970. It consolidated the Federal Water Quality Administration (formerly in the Department of Interior); the National Air Pollution Control Administration (formerly in the Department of Health, Education and Welfare, HEW); the pesticide registration, research, and standard-setting programs of the Department of Agriculture and the Food and Drug Administration; the solid-waste management programs of HEW; and some of the functions of the Federal Radiation Council and the Atomic Energy Commission for setting standards for radiation exposure. The EPA was given all the functions and responsibilities necessary to carry out the Clean Air Act and the Federal Water Pollution Control Act; and under its first administrator, William D. Ruckelshaus, it made a reasonably rapid start at doing so. [73]

His successor, Russell E. Train, continued to build an increasingly effective organization in an often difficult political environment.

Unlike CEQ, which is a small advisory group in the Executive Office of the President, the EPA is a large operating agency with a staff in 1976 of 8800 people and estimated budget outlays in that year of $3 billion. It maintains research laboratories in several parts of the country. The best concise record of the accomplishments as well as the shortcomings of the EPA are the CEQ's annual reports on the state of the nation's environment.

Occupational Safety and Health Act. As noted in Chapter 10, workers are often exposed to much higher concentrations of dangerous substances than are considered acceptable for the population at large. The main legal protection for workers is provided under the *Occupational Safety and Health Act of 1970*, which authorized the Labor Department to establish standards for exposure of workers to hazardous pollutants, to

[72]J. E. Krier, personal communication.
[73]See CEQ, *Environmental quality, 1970 and 1971*.

provide training programs, and to set up a system for reporting occupational illness and injury. These duties are carried out by the Occupational Safety and Health Administration (OSHA). The National Institute of Occupational Safety and Health (NIOSH) does research for and recommends standards to OSHA.

Three types of standards for exposure to pollutants can be set by OSHA: consensus standards adopted from a list provided by a group of government and industrial scientists, permanent standards, and temporary emergency standards. Permanent standards generally include, in addition to the eight-hour limits for worker exposure provided by consensus standards, regulations covering work practices, monitoring, and medical surveillance. Temporary standards are effective only for a six-month period, an interim during which permanent standards are developed.

By 1975, consensus standards had been set for about 400 chemicals, and OSHA and NIOSH were moving to change them to permanent standards. Permanent standards had already been established for asbestos, vinyl chloride, and a group of fourteen carcinogens; and permanent standards have been proposed for arsenic, coke-oven emissions, and noise. Some groups feel that those standards are not strict enough; for example, a chemical workers union unsuccessfully challenged in court those established for the fourteen carcinogens.

It seems certain that a constant tug-of-war will ensue between consideration of the costs (real or imagined) to industry of lowering workers' exposure to hazards and consideration of the legitimate desires of workers to protect their health. In view of the large numbers of people directly or indirectly involved (remember, hazardous materials like asbestos and plutonium can be taken home inadvertently by workers, placing their families and friends at risk), it seems clear that OSHA's activities are a long-overdue step in the right direction.

Population Law

The impact of laws and policies on population size and growth has, until very recently, largely been ignored by the legal profession. The first comprehensive treatment of population law was that of the late Johnson C. Montgomery, [74] an attorney who was president of Zero Population Growth, and whose ideas are the basis of much of the following discussion.

To date, there has been no serious attempt in Western countries to use laws to control excessive population growth, although there exists ample authority under which population growth could be regulated. For example, under the United States Constitution, effective population-control programs could be enacted under the clauses that empower Congress to appropriate funds to provide for the general welfare and to regulate commerce, or under the equal-protection clause of the Fourteenth Amendment. [75] Such laws constitutionally could be very broad. Indeed, it has been concluded that compulsory population-control laws, even including laws requiring compulsory abortion, could be sustained under the existing Constitution if the population crisis became sufficiently severe to endanger the society. Few today consider the situation in the United States serious enough to justify compulsion, however.

The most compelling arguments that might be used to justify government regulation of reproduction are based upon the rapid population growth relative to the capacity of environmental and social systems to absorb the associated impacts. To provide a high quality of life for all, there must be fewer people. But there are other sound reasons that support the use of law to regulate reproduction.

It is accepted that the law has as its proper function the protection of each person and each group of people. A legal restriction on the right to have more than a given number of children could easily be based on the needs of the first children. Studies have indicated that the larger the family, the less healthy the children are likely to be and the less likely they are to realize their potential levels of achievement. [76] Certainly there is no question that children of a small family can be cared for better and can

---

[74] Population explosion and United States law.

[75] "No state shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States, nor shall any State deprive any person of life, liberty, or property, without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws."

[76] Joe D. Wray, Population pressure on families: Family size and child-spacing, in Roger Revelle, ed., *Rapid population growth: Consequences and policy implications*, Johns Hopkins Press, Baltimore, 1971; R. B. Zajonc, *Family configuration and intelligence, Science*, vol. 192, pp. 227-236 (April 16, 1976).

be educated better than children of a large family, income and other things being equal. The law could properly say to a mother that, in order to protect the children she already has, she could

have no more. (Presumably, regulations on the sizes of adopted families would have to be the same.)

A legal restriction on the right to have children could also be based on a right not to be disadvantaged by excessive numbers of children produced by others. Differing rates of reproduction among groups can give rise to serious social problems. For example, differential rates of reproduction between ethnic, racial, religious, or economic groups might result in increased competition for resources and political power and thereby undermine social order. If some individuals contribute to general social deterioration by overproducing children, and if the need is compelling, they can be required by law to exercise reproductive responsibility -- just as they can be required to excercise responsibility in their resourceconsumption patterns -- *providing they are not denied equal protection*.

Individual rights. Individual rights must be balanced against the power of the government to control human reproduction. Some people -- respected legislators, judges, and lawyers included -- have viewed the right to have children as a fundamental and inalienable right. Yet neither the Declaration of Independence nor the Constitution mentions a right to reproduce. Nor does the UN Charter describe such a right, although a resolution of the United Nations affirms the "right *responsibly* to choose" the number and spacing of children (our emphasis). In the United States, individuals have a constitutional right to privacy and it has been held that the right to privacy includes the right to choose whether or not to have children, at least to the extent that a woman has a right to choose *not* to have children. But the right is not unlimited. Where the society has a "compelling, subordinating interest" in regulating population size, the right of the individual may be curtailed. If society's survival depended on having more children, women could be required to bear children, just as men can constitutionally be required to serve in the armed forces. Similarly, given a crisis caused by overpopulation, reasonably necessary laws to control excessive reproduction could be enacted.

It is often argued that the right to have children is so personal that the government should not regulate it. In an ideal society, no doubt the state should leave family size and composition solely to the desires of the parents. In today's world, however, the number of children in a family is a matter of profound public concern. The law regulates other highly personal matters. For example, no one may lawfully have more than one spouse at a time. Why should the law not be able to prevent a person from having more than two children?

The legal argument has been made that the First Amendment provision for separation of church and state prevents the United States government from regulating family size. The notion is that family size is God's affair and no business of the state. But the same argument has been made against the taxation of church property, prohibition of polygamy, compulsory education of and medical treatment for children, and many similar measures that have been enacted. From a legal standpoint, the First Amendment argument against family-size regulation is devoid of merit.

There are two valid constitutional limitations on the kinds of population-control policies that could be enacted. First, any enactments must satisfy the requirements of due process of law; they must be reasonably designed to meet real problems, and they must not be arbitrary. Second, any enactments must ensure that equal protection under the law is afforded to every person; they

must not be permitted to discriminate against any particular group or person. This should be as true of laws giving economic encouragement to small families as it would be of laws directly regulating the number of children a person may have. This does not mean that the impact of the laws must be exactly the same on everyone. A law limiting each couple to two children obviously would have a greater impact on persons who desire large families than it would on persons who do not. Thus, while the due-process and equal-protection limitations preclude the passage of capricious or discriminatory laws, neither guarantees anyone the right to have more than his or her fair share of children, if such a right is shown to conflict with other rights and freedoms.

It is often argued that a fetus or an embryo is a person who has a right to life, and therefore abortion as a birth-control measure must be rejected. Supporters of this argument point out that certain rights of a fetus have been legally recognized. For example, some states permit a fetus to recover money damages for personal injuries sustained before birth. Under some circumstances the common law has permitted a fetus, if subsequently born alive, to inherit property. The intentional killing of a fetus (through injury to the mother) has been declared by statute to constitute murder, although under the statute the fetus is not defined as a human being.Although some rights of the fetus after quickening have been protected in some states, most of those states require that the infant be born and living before the rights vested prior to birth actually are recognized and enforced. Most jurisdictions afford no protection to property rights or personal rights of the unquickened fetus, and no jurisdiction has protected the rights of embryos. Furthermore, analysis of the situations in which rights of the fetus have been recognized disclose that it is generally not the fetus's rights, but rather the rights of its parents or others that are being protected. For example, when a fetus did receive money damages for prenatal injuries, in reality it was the parents' and the society's economic interests that were being protected.Those who argue that a fetus has a right to life usually proceed from the assumption that life begins at or soon after conception. As stated elsewhere, the question, When does life begin? is misleading. Life does not begin; it began. The real question, from a legal as well as from religious, moral, and ethical points of view, is as follows: in what forms, at what stages, and for what purposes should society protect human life? Obviously overweight people regard their fat cells differently from their brain cells. A wandering sperm cell is not the same thing as a fertilized egg; nor is a fetus a child. Yet a fat cell, a sperm cell, a fetus, a child, an adult, and even a group of people are all human life.The common law and the drafters of the U.S. Constitution did not consider a fetus a human being. Feticide was not murder in common law because the fetus was not considered to be a human being, and for purposes of the Constitution a fetus is probably not a "person" within the meaning of the Fourteenth Amendment. Thus, under the Constitution, abortion is apparently not unlawful, although infanticide obviously is. This is a very important distinction, particularly since most rights, privileges, and duties in our society are dated from birth and not from some earlier point in time. Capacity to contract, to vote, to be drafted, to obtain Social Security rights, drivers' licenses, and the like, are all dated from birth, which is a very convenient, relatively definite point in time from which to date most rights. Certainly, the moment of birth is easier to ascertain than the moment of conception, implantation, or quickening. Such an easily ascertainable point in time is a sensible point from which to date Constitutional rights, which should not depend upon imprecisions.The fact that a fetus is probably not a "person" with Constitutional rights does not, however, mean that society has no interest in the fetus. Society

does have an interest in ensuring that an appropriate number of healthy children are born. To protect the health of the mother, some regulation of abortion is still necessary and appropriate. For example, laws requiring that abortions be performed only by qualified medical personnel in appropriately licensed institutions now exist in most states, and there are regulations governing eligibility for insurance or other financial aid.**Legal reform.** In predecessors of this book, we recommended a series of reasonable, constitutional, and desirable legal changes in the United States to discourage population growth:

1. A federal statute could be enacted that would prohibit any restrictions on safe, voluntary contraception, sterilization, and abortion, and the dissemination of information about them.
2. State and federal governments could subsidize voluntary contraception, sterilization, and abortion. Laws could require that birth-control clinics be opened at public expense in all suitable locations. They could also require that group and individual health insurance policies cover the costs of abortion and sterilization.
3. Tax laws could be revised, and new laws could be passed that would provide incentives for late marriage,

small families, and alternative roles for women. The tax disadvantage to single, childless persons could be eliminated.
4. State and federal laws could make sex education, including instruction about contraception, mandatory in all schools, and the government could sponsor public education programs designed to encourage people to want fewer children.
5. Federal support and encouragement for the development of more effective birth-control drugs and devices could be greatly increased.

We are pleased to report that between 1970 and 1975 all of these changes took place, at least to some degree. Much of what remains to be done consists of extending or more fully implementing programs that now exist. The only real exception is mandatory sex education, but even on a voluntary basis the trend is toward expansion, and there is support and encouragement both from the Department of Health, Education and Welfare and from private organizations such as the Sex Information and Education Council of the United States (SIECUS).

If these relatively uncoercive policies should fail to maintain a low American birth rate, more coercive laws might well be written (see Chapter 13 for examples). At the moment, there might be little justification or public support for such laws, but if the resource and environmental situations are allowed to deteriorate, popular support might develop rapidly. There has been considerable talk in some quarters at times of forcibly suppressing reproduction among welfare recipients (perhaps by requiring the use of contraceptives or even by involuntary sterilization). This may sadly foreshadow what our society might do if the human predicament gets out of hand. We hope that population growth can be controlled in the United States without resorting to such discriminatory and socially disruptive measures. That, in fact, has been one purpose of this and our previous books -- to stimulate population control by the *least* coercive means before it is too late. The decline in birth rates in the United States and other developed countries since 1970 is a most hopeful sign that population control can be easily achieved in those countries, but we must reiterate that the United States and most other DCs are still a long way from zero population growth.

BUSINESS, LABOR, AND ADVERTISING

Although legal and legislative action are essential to the solution of pollution problems in the United States, it is to be hoped that American industries will not wait to be coerced into responsible behavior. In fact, a few industries took the initiative for cleaning up their effluents before it was legally required, and some found it possible to make profits from pollution by-products. Such unexpected bonuses are not possible in all cases, of course. Tax incentives and government subsidies for cleaning up pollution may be applied when costs are high, but in the long run abating pollution will best be achieved as a part of a complete overhaul of our tottering economic system.

Meanwhile, many industrial organizations are exploring technological methods for dealing with various kinds of pollution; indeed, new companies have appeared whose entire business is pollution abatement or waste disposal of one sort or another. On the preventive side of the coin, environmental consulting firms have begun to appear. Their business is to advise communities and businesses in planning development with the least possible damage to the environment and the most benefit to the human inhabitants. Many of them are involved in writing the environmental impact statements required by the NEPA and several states. These trends and others, such as research on recyclable or biodegradable containers, should certainly be encouraged.

Labor

Labor also has an important role to play in easing the pressure on the environment. In the United States an unfortunate "jobs versus the environment" attitude was promoted as the mid-1970s recession developed. Many business and labor leaders, believing that the only solution to problems of unemployment was to fire up the old ecologically destructive economic machine once again, lobbied for the relaxation of measures to protect the environment. The basic message of environmentalists that not only were many jobs threatened by the continuing rape of the environment, but that many lives, and indeed the persistence of civilization, were threatened also, obviously had not penetrated.

Environmental protection in reality has proven to be

far more a creator of jobs than a destroyer. The Council on Environmental Quality in 1975 estimated that through 1974 fewer than 14,000 workers had lost their jobs as a result of environmental controls, most of them through closure of plants that were obsolescent, inefficient, and already only marginally profitable. In most cases environmental controls only hastened the inevitable. But, although a precise estimate would be difficult to make, it is clear that thousands more jobs have been created by environmental protection. Building and modernizing urban sewage systems alone provides perhaps 85,000 jobs for each $1 billion spent. People are needed to administer and enforce environmental programs and to build, install, operate, and maintain pollution abatement equipment, and so forth. [77]

Labor should be among the leaders in the movement to maintain environmental quality, even though workers, along with the rest of society, will have to pay part of the costs. Many more working people are exposed to environmental hazards, from poor safety standards in workplaces to smog, than are industrialists and bankers who work in plush, air-conditioned offices and can afford to live beyond the smog belt.

In Australia, labor has moved into the forefront, battling against development of Australia's uranium deposits and against other projects deemed socially or environmentally injurious. Led by Jack Mundey, a leader in the building trades in New South Wales, "Green Bans" have been instituted, in which union members simply refuse to work on such projects. [78] In 1974 many millions of dollars' worth of construction work was being held up by Green Bans in Sydney alone. If only such a sense of social responsibility pervaded the labor movement everywhere!

There is every reason to believe that in years to come environmentalists and workers (two groups whose interests already greatly overlap) more and more will find their interests becoming congruent. For example, environmentalists are increasingly concerned about the energy-intensiveness of our economic system -- as are many people in the labor movement as they see energy being substituted for workers. The important idea that improvements in energy efficiency not only spare the environment (by reducing energy requirements) but also increase employment is well illustrated in the following discussion by Schipper:

Compare, for example, two air conditioners of equal capacity, operating in similar homes under similar loads in the same climatic region, one requiring half the power of the other. If a consumer buys the more efficient unit, some of the money otherwise spent on energy is used for extra materials and labor, and this expenditure results in a more carefully constructed, more efficient air conditioner. Since manufacturing is generally more labor-intensive than electric utilities, the redirection of spending -- from paying for electricity to investment in a more efficient unit -- raises the total demand for labor per unit of air conditioning and still provides for the consumer's desire for comfort. [Moreover] when the consumer spends the money saved by energy conservation, the new purchase will require increased labor in comparison to buying electricity. The result is more goods or services and more employment, with less energy consumed. [79]

Higher energy costs, which are now resulting from the appearance in the balance sheets of the costs of depletion and pollution, increase the potential savings and employment benefits derivable from greater energy efficiency (see also Chapter 8).

A reorientation of business, labor, and consumer values is obviously in order. Resources of all kinds are limited, but Americans behave as though they were not. The neglected virtues of economy and thrift must be restored to the pedestals that they once occupied in this country.

Advertising

Advertising plays a leading role in perpetuating the American system of consumerism. Whether the blame for this lies largely with industry or with the consumers is difficult to determine and probably does not much matter. What does seem evident is that advertising does not *have* to be

mostly antienvironmental. In the late 1960s many advertisements began to appear featuring various companies' efforts at pollution abatement. Such

[79]Lee Schipper, Raising the productivity of energy use.

concern over the corporate image with respect to pollution was no doubt a necessary first step, but more than advertising of environmental protection is required.

Environmentalists have been increasingly irritated by self-serving ads showing how Company XX has always been deeply involved in protecting the environment. Those emanating from oil companies -- among the greatest destroyers of the environment -- are especially galling. Ads from pollutors posing as environmentalists have been christened "ecopornography." Much more acceptable are ads that offer useful information to consumers on how they can cooperate with business in environmentally beneficial projects, such as energy conservation or recycling materials. While we certainly do not condone heavy promotion of new versions of products whose environmental contribution is negligible or questionable, such as certain gasoline additives or disposable flashlights, we welcome ads that feature genuine improvements, such as unleaded gasolines or non-aerosol spray containers. Admittedly, the line dividing such cases is not always easy to draw.

The advertising industry can do much more than it has so far to encourage its clients to promote products by stressing such qualities as durability, economy, and versatility. For example, automobile advertising should emphasize economy of purchase and operation, especially low gasoline consumption, durability, compactness, comfort (but not massiveness -- interior room can be maintained even as weight is greatly trimmed), engine efficiency, safety, and low pollution emissions. For a time after the energy crisis of 1974 the trend was in that direction, but by 1976 there was a move back toward the bad old days. Advertising that stresses large size and high power in cars should be permanently discontinued.

Beyond cooperating with clients in antipollution promotions, advertising companies could by agreement refuse to design ads promoting wasteful or polluting products -- for example, ads featuring throwaway products, food in throwaway cans and bottles, or goods wrapped in unnecessary layers of packaging. Above all, every effort should be made to expunge from advertising the idea that the quality of life is closely related to the rate at which new products are purchased or energy is consumed.

Advertising agencies can also make a contribution to the population situation by refusing to produce ads featuring large families. Under pressure from population and women's organizations, some of the obvious changes have already been made in ads for many products. Other ways have been found to promote heavy-duty washing machines than as an item for large

families -- dormitories, hospitals, and other institutions use them also, for instance. Families with three or more children have lately been depicted as large families, and the two-child family appears the norm. Women are increasingly featured playing roles other than homemaker and mother, and the convenience of many goods is being stressed more as a value for working women than for the overburdened mother, as they once were exclusively. This trend should be encouraged.

The critical problem, of course, is to find a way to swing both advertising clients and agencies in the right direction. While public utilities, for example, could and should be prohibited from promoting greater use of electric power through advertising, similar legal controls over all advertising would undoubtedly prove too cumbersome.

A court decision in August 1971 [80] held that, under the fairness doctrine, radio and television stations that carry advertising for big, high-horsepower cars also must broadcast information about the environmental threat such cars represent. The suit had been brought by Friends of the Earth and the Environmental Defense Fund after the Federal Communications Commission had ruled against such a policy. If it were widely applied, this interpretation of the fairness doctrine might discourage manufacturers and advertisers from promoting socially and environmentally undesirable products; to date, unfortunately, it has not been widely applied.

The late 1970s and early 1980s will be crucial years for everyone. The business community in the United States and around the world is faced with a particularly difficult choice. It can continue to pursue the economic goals of the past decades until either an environmental disaster overtakes civilization or until governments and the public compel a change; or it can actively initiate novel approaches to production and industry, with a view to protecting the environment, preserving limited resources, and truly benefiting humanity.

ECONOMIC AND POLITICAL CHANGE

Practical men, who believe themselves to be quite exempt from any intellectual influences, are usually slaves to some defunct economist. Madmen in authority, who hear voices in the air, are distilling their frenzy from some academic scribbler of a few years back.

--John Maynard Keynes, 1936

In relation to the population-resources-environment crisis, economics [81] and politics can usually be viewed as two sides of a single coin. A very large number of political decisions are made on an economic basis, especially those relating to environmental and resource problems. Illustrating the influence of economics, Lord Keynes wrote (in the lines just preceding the epigraph of this chapter): "The ideas of economists and political philosophers, both when they are right and when

they are wrong, are more powerful than is commonly understood. Indeed the world is ruled by little else." [82] If anything, his statement is even more true today than it was then.

Economics nevertheless is sometimes wrongly blamed for political problems. Although the major political division of the developed world -- that between capitalist and communist nations -- is thought to be based on differences in economic ideology, the actual differences are relatively few. A major cause of humanity's current plight lies not in the economic differences between those two political spheres but in the economic attitudes that they hold *in common*.

Gross National Product and Economic Growthmanship

Economists are not unanimous in their views of economic growth. Some have perceived that perpetual economic growth is as impossible to sustain as perpetual population growth. Herman Daly in 1975 told a Congressional committee:

In 1936 John Maynard Keynes remarked that "The part played by orthodox economists, whose common sense has been insufficient to check their faulty logic, has been disastrous to the latest act." The same words ring true in 1975. It is easy to be trapped by the excessive rigidity of our own values and goals. The South Indian Monkey Trap, for example, works solely on the basis of rigid goals. A hollowed-out coconut is filled with rice and fastened by a chain to a stake in the ground. There is a hole in the coconut just large enough to allow the monkey to insert its extended hand, but not large enough to permit withdrawal of his clenched fist full of rice. The monkey is trapped by nothing more than his refusal to let go of the rice, to reorder his goals, and to realize that in the given circumstances his freedom is more important than the fistful of rice. We seem to be trapped in a growthdominated economic system that is causing growing depletion, pollution, and disamenity, as well as increasing the probability of ecological catastrophe. We must open our collective fist and let go of the doctrine of perpetual growth, or else we will be caught by the consequences. [83]

In the 1967 edition of his classic economics text, by contrast, Paul A. Samuelson of M.I.T. wrote: "The ghost of Carlyle should be relieved to know that economics, after all, has not been a dismal science. It has been the cheerful, but impatient, science of growth." [84] In 1976, viewing the prospects for continued economic growth in the United States and the rest of the world, he still found them cheering. [85] The majority of economic theorists agree with Samuelson, as do most businessmen and politicians. Some economists besides Daly have questioned the growth ethic, however. For example, E. J. Mishan stated in 1967:

The skilled economist, immersed for the greater part of the day in pages of formulae and statistics, does occasionally glance at the world about him and, if

[81] For a general review of orthodox economics, we recommend the latest edition of Paul A. Samuelson's fine text, *Economics* (latest edition at this writing, the tenth, 1976). For a more detailed treatment of environmental economics, see Richard Lecomber, *Economic growth versus the environment*. For the latter, familiarity with economic concepts such as indifference curves and inferior goods (explained in Samuelson) is required.

[82]*The general theory of employment, interest, and money*, Harcourt, New York, 1964 (originally published in 1936).
[83]Herman E. Daly, in testimony before the Joint Economic Committee of Congress, hearings on economic growth, October 23, 1975.
[84]*Economics: An introductory analysis*, McGraw-Hill, New York, 1967.
[85]"Limits to growth: What lies ahead?" *Honolulu Advertiser*, March 15, 1976. In fairness to Samuelson, part of his cheer was engendered by the declining rate of population growth in the United States.

perceptive, does occasionally feel a twinge of doubt about the relevance of his contribution. . . . For a moment, perhaps, he will dare wonder whether it is really worth it. Like the rest of us, however, the economist must keep moving, and since such misgivings about the overall value of economic growth cannot be formalized or numerically expressed, they are not permitted seriously to modify his practical recommendations. [86]

GNP. In much of the world -- indeed, in all countries with any aspirations toward modernization, progress, or development -- a general economic index of advancement is growth of the gross national product (GNP). The GNP is the total national output of goods and services valued at market prices. Stated another way, it consists of the sum of personal and government expenditure on goods and services, plus the value of net exports (exports minus imports) and private expenditure on investment. It can be a very useful economic indicator.

More important than what the GNP is, however, is what it *is not*: it is not a measure of the degree of freedom of the people of a nation; it is not a measure of the health of a population; it is not a measure of the equity of distribution of wealth; it is not a measure of the state of depletion of natural resources; it is not a measure of the stability of the environmental systems upon which life depends; it is not a measure of security from the threat of war. It is not, in sum, a comprehensive measure of the *quality* of life, although, unhappily, it is often believed to be.

When the standards of living of two nations are compared, it is customary to examine their *per-capita* GNPs. Per-capita GNP is an especially unfortunate statistic. First of all, it is the ratio of two statistics that are at best crude estimates, especially in the LDCs where neither GNP nor population size is known with any accuracy. More important, comparisons of per-capita GNP overestimate many kinds of differences. For instance, a comparison of per-capita GNPs would lead to the conclusion that the average person in the United States lives almost 10 times as well as the average Portuguese and some 60 times as well as the average Burmese. This, of course, is meaningless, since virtually all services and some goods are much cheaper in the LDCs, and GNP calculates only what enters the recorded money economy. Americans pay perhaps 5 or 10 times as much for farm labor, domestic help, haircuts, carpentry, plumbing, and so forth as do people in the LDCs, and the services in the United States may be of inferior quality. And yet, because of the accounting system, those services contribute between 5 and 10 times as much to our GNP as the same services do to the GNPs of, say, Burma or India.

Furthermore, figures on the increase of per-capita GNP in LDCs do not take into account such things as rise in literacy rate, and thus may underrate the amount of progress a country has made toward modernization. Nor does the GNP measure many negative aspects of the standard of living. Although the average Burmese unquestionably lives much less well than the average person in the United States, the average American may cause 100 times as much ecological destruction to the planet.

Another problem with GNP and per-capita GNP reckoning is that they are measures devised by and for DCs, in which accurate government record-keeping is an established tradition and virtually all of a society's productive activity enters the money economy, where it is recorded and can be totaled. Yet even in the United States, agricultural, dairy, and livestock production consumed on the farm either is ignored or loosely estimated in the calculation of our total food production. This does not significantly affect decisions based on food production because production for consumption on the farm represents only a small part of overall United States food production (even though it would still account for millions of dollars' worth of food). In an LDC, where subsistence agriculture, home manufacture of household items, barter, and money transactions too small and casual to be noted are the rule, an analysis of the overall situation by government-published production records can and commonly does lead to very serious misjudgements about the real condition of an economy and society.

Finally, it must be remembered that the per-capita GNP statistic can and often does conceal gross inequities *within* countries in the distribution of goods and services. This makes it an even more fallible index of well-being.

---

[86] *The costs of economic growth*, pp. ix-x, Praeger, New York.

Growthmanship. A serious criticism that can be leveled at the majority of economists applies equally to most people and societies: they accept a doctrine of economic determinism. The myths of cornucopian economics, as opposed to the realities of geology and biology, have already been discussed, but the problem is much more pervasive than that. Economic growth has become *the* standard for progress, *the* benefit for which almost any social cost is to be paid.

This prejudice in economic thought can be fully appreciated by a perusal of Samuelson's *Economics*. The book, of course, is oriented toward economic growth. The increasing scarcity of nonrenewable resources is presented in it only briefly as a problem of less developed countries. The eventual physical constraint placed on material growth by the conversion to heat of all the energy people consume is not discussed in the text, nor are the more imminent environmental constraints considered in our earlier chapters. Implicit in Samuelson's treatment of economic development is the idea that it is possible for 5 billion to 7 billion people to achieve a standard of living similar to that of the average American of the 1960s. Excessive technological optimism is explicit or implicit throughout the book.

Nevertheless, Samuelson's text reveals more understanding of problems related to population size and environmental quality than the writings of many other economists. He does realize that

growth of GNP must be "qualified by data on leisure, population size, relative distribution, quality, and noneconomic factors." In the 1970 edition, Samuelson added two chapters dealing with economic inequality, the quality of life, and problems of race, cities, and pollution. Furthermore, in 1969 Samuelson wrote:

Most of us are poorer than we realize. Hidden costs are accruing all the time; and because we tend to ignore them, we overstate our incomes. Thomas Hobbes said that in the state of nature the life of man was nasty, brutish and short. In the state of modern civilization it has become nasty, brutish and long. [87]

Most economists subscribe to the "bigger and more is better" philosophy: the growing mixed economy is something to analyze, improve, and by all means to keep growing. In an article that appeared in the *New York Review of Books*, Nobel laureate economist Wassily Leontief of Harvard remarked, "If the 'external costs' of growth clearly seem to pose dangers to the quality of life, there is as yet no discernible tendency among economists or economic managers to divert their attention from this single-minded pursuit of economic growth." [88]

Indeed, when those external costs (various kinds of environmental and social deterioration) do come to the attention of economists, *growth* is seen as the way to deal with them. Walter Heller, once chairman of the President's Council of Economic Advisers, has stated, "I cannot conceive a successful economy without growth." [89] Accordingly, he urges expansion of the United States economy so that resources will become available to fight pollution. Heller, like many other economists, confuses more of the disease with the cure!

That economists have clung to their "growthmania" is not surprising, however. After all, natural scientists often cling to outmoded ideas that have produced far less palpable benefits than the growing mixed economies of the Western world in the twentieth century. The question of whether a different economic system might have produced a more equitable *distribution* of benefits is not one that Western economists like to dwell on. Furthermore, the idea of perpetual growth is congruent with the conventional wisdom of most of the businessmen of the world; indeed, of most of the world's population.

The people of the LDCs naturally wish to emulate the economic growth of the West, and they long for "development" with all its shiny accoutrements. Why should they be expected to know that it is physically and ecologically impossible for them to catch up with the United States when many of the "best informed" Americans are still unaware of that fact? Before attempting to pursue the Western pattern of development, perhaps they should contemplate Heller's belief that the best

---

[87] *Newsweek*, October 6, 1969.

[88] Quoted in Ehrlich and Ehrlich, *Population, resources, environment*, 2nd ed., p. 382.

[89] Undoubtedly an accurate statement. This quote and some of his other views are cited in E. F. Schumacher, *Small is beautiful; Economics as if people mattered*, pp. 111-112. For direct access to the views of Heller and other modern growthmen, see his *Perspectives on economic growth*. See also William Nordhaus and James Tobin who conclude in *Is growth obsolete?*

that it is not, and that GNP is a pretty good measure of "secular progress." For a wonderful (if unintentional) parody of the writing of an uninformed economist, see Norman Macrae, *America's third century*.

hope for pulling the United States out of its environmental difficulties is yet more growth -- even though the United States already co-opts some 30 percent of the world's resource use. Under that prescription, even catching up would not suffice.

New approaches to the national product. It is by now abundantly clear that the GNP cannot grow forever. Why should it? Why should we not strive for zero economic growth (ZEG) as well as zero population growth? As John Kenneth Galbraith pointed out in *The new industrial state*, it would be entirely logical to set limits on the amount of product a nation needs and then to strive to reduce the amount of work required to produce such a product (and, we might add, to see that the product is much more equitably distributed than it is today). Of course, such a program would be a threat to some of the most dearly held beliefs of this society. It would attack the Protestant work ethic, which insists that one must be kept busy on the job for forty hours a week. It is even better to work several more hours moonlighting, so that the money can be earned to buy all those wonderful automobiles, detergents, appliances, and assorted gimcracks that *must* be bought if the economy is to continue to grow. But this tradition is outmoded; the only hope for civilization in the future is to work for *quality* in the context of a nongrowing economy, or at least an economy in which growth is carefully restricted to certain activities. [90]

A number of interesting suggestions about GNP have been made by economist Edwin G. Dolan in his fine little 1969 book, *TANSTAAFL: The economic strategy for environmental crisis*. TANSTAAFL (which stands for There Ain't No Such Thing As A Free Lunch) contains a lucid consideration of population-environment economics, and we recommend it, even though we differ with the author on some points. Dolan, along with some other economists, would rename the GNP the gross national cost (GNC). [91]

More important, Dolan would distinguish between two types of GNC. Type I GNC would measure that fraction of GNC produced with renewable resources and recycling of wastes. Type II GNC would be that depending on the depletion of nonrenewable resources and the production of indestructible wastes. The problems of discrimination might be difficult (consider, for instance, calculating the energy component involved in the production of Type I GNC), but the basic aim is sound. As Dolan says, "Politicians and economists would then design their policies to maximize Type I and minimize Type II. In the eyes of world opinion a high Type I component would be a source of national pride, while high production of the Type II variety would be a source of shame."

In a more technical vein, economists William Nordhaus and James Tobin, recognizing the problems inherent in GNP as a measure of what people value, have suggested some tentative (and sensible) modifications in GNP to produce a measure of economic welfare (MEW). [92] Their discussion gives hope that better economic measures can and should be developed -- even though it is obvious to them and other thoughtful economists that no single measure of economic welfare is ever going to be fully satisfactory. [93]

The problem of finding even a partially satisfactory measure of total welfare, or quality of life (QOL), is infinitely more difficult. [93a] Beyond the question of refining the concept of GNP as a measure (or perhaps, more realistically, of disseminating the limitations of its usefulness throughout the economic, business, and political communities, which all too often act as though maximizing GNP were the ultimate human value), lies a more important issue. That is the perception by many people that the relationship between GNP and QOL has become negative; as GNP rises, QOL declines. [94]

Since there is no agreed-upon measure of QOL, this perception is unlikely to be tested by classical economic methods -- but that does not mean that the phenomenon is not real. Perhaps the attempts by economists to refine the

[92] Is growth obsolete?

[93] See, for example, Arthur M. Okun, *Social welfare has no price tag*.

[93a] An extensive discussion of the problem of defining QOL is contained in Peter W. House, *The quest for completeness: Comprehensive analysis in modeling, indicators, gaming, planning and management*.

[94] P. R. Ehrlich and R. Harriman, *How, to be a survivor: A plan to save Spaceship Earth*.

concept of GNP or to define QOL [95] eventually will permit a more precise tracking of the relationship, but it seems unlikely that human social systems or the ecological systems of the planet can afford to wait. We suspect that the era of indiscriminate growth will come to an end soon -- preferably through political action generated by subjective perceptions of declining QOL by large numbers of people -- but if not, by the intervention of ecocatastrophes. Hints of the former could be seen in such phenomena as the popularity in 1976 of California governor Jerry Brown's "limits to growth" campaign for the presidency.

Cost-benefit analyses. One of the problems with growthmania is that for too long the penalties of growth have been ignored by the economic system. Cost-benefit calculations until very recently were done with too narrow an outlook and over too short a time span.

For example, consider the history of a contemporary housing development. A developer carves up a southern California hillside, builds houses on it, and sells them, reaping the benefits in a very short time. Then society starts to pay the costs. The houses have been built in an area where the native plant community is chaparral (Chapter 4). Chaparral, known to plant ecologists as a "fire climax," would not exist as a stable vegetation type unless the area burned over occasionally. When it does, the homes are destroyed, and the buyers and the public start paying hidden costs in the form of increased insurance rates and emergency relief.

Of course, there are hidden costs even in the absence of such a catastrophe. A housing development puts a further load on the water supply and probably will be a contributing political factor in the ultimate flooding of distant farmland to make a reservoir. Perhaps wind patterns cause smog to be especially thick in the area of the development, and as it begins to affect the inhabitants they and society pay additional costs in hospital bills and high life-insurance premiums. And, of course, by helping to attract more people into the area, the development helps to increase the general smog burden.

Then there are the problems of additional roads, schools, sewage-treatment plants, and other community requirements created by the subdivision. While the builder may have put the roads in the subdivision, increased taxes must pay for increased upkeep on roads in the subdivision area, and eventually for new roads demanded by increasing congestion. Among the saddest phenomena of our time are the attempts by politicians and chambers of commerce to attract industry and developers to their areas to "broaden the tax base." The usual result, when the dust has settled, is that the people who previously lived in the area have a degraded environment and *higher* taxes.

In short, the benefits are easily calculated and quickly reaped by a select few; the costs, on the other hand, are diffuse, spread over time, and difficult to calculate. For example, how would one assess the cost of weather modification by pollution, which might result in the deaths of millions from starvation? What is the value of an ecological system destroyed by chlorinated hydrocarbons? What is the value of one life lost to emphysema?

The disparity between the few elements accounted for in present methods of cost-benefit analysis and the real costs borne by society is even more obvious when the problem of industrial pollution is considered. Here the benefit is usually the absence of a cost. Garbage is spewed into the environment, rather than being retained and reclaimed. The industry avoids real or imagined financial loss by this process. The term *imagined* loss is used because some industries have found that reclaiming pollutants has more than paid for the cost of retaining them. More often than not, however, the industry benefits from pollution, and the public pays the shortand long-term costs. Air pollutants damage crops, ruin paint, soil clothes, dissolve nylon stockings, etch glass, rot windshield-wiper blades, and so on. Pollutants must be removed, often at considerable expense, from water supplies. People with emphysema, lung cancer, liver cancer, and hepatitis must be given expensive hospitalization. Insurance costs go up. In these, and in myriad other ways, *everyone* pays.

Perhaps the most subtle and least appreciated costs are those society must shoulder when it damages or destroys ecosystems that formerly performed essential free services. For example, destruction of natural areas, espe-

[95] See, for example, Lowdon Wingo, *The quality of life: Toward a microeconomic definition*. See also the discussions in Chapter 12 and below of the connections between quality of life and diversity of personal options, and Richard Easterlin's fascinating Does economic growth improve the human lot?

cially forests, can change climate locally, often resulting in greater frequency and intensity of floods and droughts and a need for water management projects. Soil erosion can be greatly accelerated, leading to silting of streams and lakes, with damage to fisheries and polluted water supplies. With the loss of the air purifying functions of ecosystems, air pollution is increased. [95a]

These costs are what accountants euphemistically call external diseconomies, because they are external to the accounting system of the polluter. A persuasive case can be made that, at an advanced stage of industrialization, the diseconomies far outweigh the benefits of growth. Such a case was made in detail by economist Ezra Mishan some years ago and refined since. [96]

That the costs to society of pollution and environmental destruction far exceed those of abatement or prevention is no longer in serious doubt. U.S. national pollution-control expenditures for 1972, both public and private, amounted to $19 billion; the annual costs of just air and water pollution were variously estimated (so far as they could be) in a range from $10 billion to $50 billion around 1970. [97] And those estimates probably left out many of the indirect costs, which are often impossible to sort out from other causes, and some for which there is no price tag, such as aesthetic value.

The simplest way to attack external diseconomies directly is to require industry to internalize them. Companies can be forced by law to absorb the costs of greatly reducing the release of pollutants. Profits would then be added on after *all* costs were paid. Clearly, the most sensible solution in most cases is for society to insist on pollution abatement *at the source*. It is cheaper in every way to curtail it there, rather than attempt to ameliorate the complex problems pollutants cause after they are released into the environment.

Society, having permitted the pollution situation to develop, should also shoulder some of the burden of its correction. As a theoretical example, Steel Company X, located on the shores of Lake Michigan, is pouring filth into the lake at a horrendous rate. A study shows that it would cost two dollars per share of common stock to build the necessary apparatus for retaining and processing the waste. Should the company be forced to stop polluting and pay the price?

Certainly it must be forced to stop, but it seems fair that society should pay some of the cost. When Company X located on the lake, everyone knew that it would spew pollutants into the lake, but no one objected. The local people wanted to encourage industry. Now, finally, society has changed its mind, and the pollution must stop. But should Company X be forced into bankruptcy by pollution regulations, penalizing stockholders and putting its employees out of work? Should the local politicians who lured the company into locating there and the citizens who encouraged them not pay a cent? Clearly society should order the pollution stopped *and pick up at least part of the bill*. It would be a bargain in the long run; society is already paying a much higher cost for the pollution.

Such a situation actually occurred in 1971. Congress refused to vote funds for the continuance of the SST project, in part because of environmental considerations. As mentioned earlier, the decision cost thousands of existing jobs and even more potential jobs. Society must find mechanisms to compensate people who lost jobs in such a way, and it must retrain and, if necessary, relocate them. Such dislocations are certain to occur more often and on a larger scale

as polluting, energy-wasting, and socially dangerous industries and projects are phased out. Fortunately, time should be available to smooth the transitions in most situations.

It has become obvious that one needed change in the economic system is to adopt a new method of costaccounting that fully incorporates such items as resource depletion and environmental degradation, even though such a change might involve grave political repercussions.

Economics, Resources, and the Environment

The Bucky Fulfilling dreams of technologically based abundance of the sixties now seem adolescent and remote.

-- Hazel Henderson, *Planning Review*, April/May 1974

[96]*The costs of economic growth*; Ills, bads, and disamenities: The wages of growth.
[97]CEQ, *Environmental quality, 1975*, pp. 496-543.

Economist Kenneth Boulding once described the present economic system of the United States as a *cowboy economy*. [98] The cowboy metaphor refers to a reckless, exploitive philosophy based on two premises: more resources are waiting just over the horizon, and nature has a boundless capacity to absorb garbage. For practical purposes, those premises were valid in the days of the American frontier. In that world it made some sense to seek rapid improvements in human welfare strictly through economic growth, with little regard for what *kind* of growth or for the sorts of waste that accompanied it.

But today the old premises are wrong. It is now clear that physical resources are limited and that humanity is straining the capacity of the biological environment to absorb abuse on a global scale. The blind growth of a cowboy economy is no longer a viable proposition -- even though, as noted above, an astonishing number of economists (and others) still cling to the belief that it is.

The accepted measure of success in a cowboy economy is a large throughput. *Throughput* refers to the rate at which dollars flow through the economy and, insofar as dollar flow depends on the sale of physical goods rather than services, to the speed with which natural resources are converted into artifacts and rubbish. A conventional indicator of throughput is the GNP.

Boulding has described a rational alternative to the GNP-oriented cowboy economy, calling this alternative the *spaceman economy*, in harmony with the concept of Spaceship Earth. Consistent with the finiteness of this planet's supply of resources and the fragility of the biological processes that support human life, such an economy would be nongrowing in terms of the size of the human population, the quantity of physical resources in use, and human impact on the biological

environment. The spaceman economy need not be stagnant, however; human ingenuity would be constantly at work increasing the amount of actual prosperity and well-being derivable from the fixed amount of resources in use.

Quite the opposite of the cowboy economy, which thrives on throughput, the spaceman economy would seek to minimize the throughput needed to maintain its stable stock of goods. This is an obvious goal for any economy as regards population. A given population size can be maintained by a high birth rate balanced by a high death rate (high throughput) or by a low birth rate balanced by a low death rate (low throughput). Most people would agree that the low-throughput situation is preferable. Applying this to material goods, the "birth rate" is the production rate and the "death rate" is the rate at which the goods wear out or become obsolete. A given level of affluence, measured in terms of the stock of goods per person, can be maintained by very different levels of resource flow. Thus, a society with one refrigerator for every three people can maintain this level of affluence with refrigerators that need replacement every ten years (high throughput) or every forty years (low throughput).

Quality of life in a spaceman economy. Could people's desires for material comforts and a high quality of life be met in a spaceman economy? There are good reasons to believe the answer is yes. With an unchanging number of people, society's efforts can be devoted entirely to improving conditions for the population that exists, rather than to struggling to provide the necessities of existence for new additions. Moreover, focusing attention on the *quality* of a fixed stock of goods in a spaceman economy is in many respects a more direct route to prosperity than emphasizing throughput in a cowboy economy. This is so because, as Boulding has argued, *quality* of stock is often a better measure of well-being than throughput. Most people would rather own one Rolls Royce than a succession of Fords.

Furthermore, once a good diet, adequate housing, clean water, sanitation facilities, and a certain basic level of well-made material goods have been provided, quality of life becomes largely a matter of the availability of services and personal options. Services include education, medical care, entertainment and recreation, fire and police protection, and the administration of justice. Services do involve the use of material resources and do affect the environment. For example, commercial office space, much of it associated with the provision of services, is a major consumer of electricity for lighting, heating, and air conditioning. Nevertheless, there is great potential for improving and extending services while reducing the associated material, energy, and environmental demands.

---

[98]The economics of the coming Spaceship Earth.

Personal options consist of access to a variety of landscapes, living accommodations, career possibilities, cultural environments, recreational opportunities, interpersonal relationships, degrees of privacy, and so forth. Personal options are an important part of the quality of an individual's life even when they are not exercised -- it pleases us to know we *could* live in the country, even though we may choose to live in cities. Options also have value beyond the preferences of the majority of people in any given society. If the majority of citizens preferred an

urban environment, that would not be sufficient reason to transform all living areas of the planet into urban environments -- this is tyranny of the majority. Even those who enjoy neither canoeing nor golf should concede that a society with room for golf courses and free-flowing rivers is preferable to a society without those options. It is even reasonable to suppose that in human society diversity on a small scale (individual choice) promotes stability on a large scale (society as a whole).

Insofar as personal options are part of quality of life, the spaceman economy is a clear choice over the cowboy economy. Population growth and the transformation of an ever larger fraction of the biosphere to maintain the growth of throughput are destroying options in the United States now and for the future. By stabilizing the population and reducing the level of environmentally disruptive activities associated with throughput of resources, the spaceman economy would preserve remaining options; by focusing on services and finding new ways that "people can live more gently on the Earth," [99] it would create new ones.

Converting to a spaceman economy. How can the world society make the transition from a cowboy economy to a spaceman economy? How do we get from here to there? Population control, of course, is absolutely essential, with an eventual target of a *smaller* population than today's. [100] Another task that must be faced squarely is the redistribution of wealth within and between nations. Otherwise, fixing the quantity of physical goods in use would freeze the majority of human beings in a state of poverty.

Within rich countries such as the United States, the problem could be alleviated by a relatively moderate amount of redistribution. Economist Herman Daly has called for the establishment of a *distributist institution*, which would limit the range of financial inequity in the United States. He suggests establishing maximum and minimum incomes, arguing, "Most people are not so stupid as to believe that an income in excess of say $100,000 per year has any real functional justification . . . especially . . . when the high paid jobs are also usually the most interesting and pleasant." He would also limit personal and corporate wealth and then "put responsible social limits on the exercise of monopoly power by labor unions, since the countervailing monopoly power of corporations will have been limited." [101]

The critical question, of course, is how to get around the extraordinary power interests that would be unalterably opposed to maximum income limits and (if possible) even more opposed to direct taxation of wealth. Greed and the desire for power are extraordinarily strong forces against any serious attempts to curb income and wealth, and many conventional economists (with their hands firmly clenched on Daly's symbolic rice) would oppose such limitation on the grounds that it would kill the incentive system that keeps the economy growing. Daly suggests gradual implementation as a strategy -- and perhaps that could be made to work, since the *principles* of progressive income taxation and some sort of "floor" under individual income are rather well established in our society. The real sticky wicket would be direct taxation of wealth, since that would threaten the entrenched power of the Rockefellers, Carnegies, Fords, Kennedys, and countless other beneficiaries of enterprising and acquisitive ancestors. But once some system of further redistribution were established in the United States, it would then be justifiable to implement a transition to a spaceman economy as quickly as possible.

In the poor countries, a degree of careful expansion of productive activities -- that is, continued economic growth sufficient to raise per-capita living standards -- as

[100] See, for example, Emile Benoit, "A dynamic equilibrium economy", *Bulletin of the Atomic Scientists*, February 1976; Ehrlich and Ehrlich, *Population, resources, environment*, 1st ed., p. 322.

[101] *Testimony before the Joint Economic Committee of Congress*, October 23, 1975, pp. 10 and 11; see also the book he edited, *Toward a steady-state economy*.

[99] See S. Page, Jr., and W. Clark, *The new alchemy: How to survive in your spare time*.

well as massive transfers of goods and technical assistance from the rich countries (see Chapter 15) will be necessary before the notion of a spaceman economy can be seriously entertained. It is clear that redistribution alone would be insufficient to give all human beings an acceptable standard of living -- at least, acceptable by today's DC standards. That would mean a per-capita GNP of only about $1000, even if population size were also frozen at 4 billion.

Reducing throughput. The strategy of converting productive capacity from frivolous and wasteful enterprises to legitimate social needs should be accompanied, even in the short term, by efforts to minimize the throughput of resources associated with production. Herman Daly has suggested a specific mechanism for accomplishing such a reduction: putting strict *depletion quotas* on the natural resources of the United States. [102] That is, limits would be placed on the total amount of each resource that could be extracted or imported by the United States each year. This would not only directly reduce the pressure Americans place on the resources of the planet, but would also automatically generate a trend toward recycling and pollution abatement. With resources scarce (and thus expensive), a premium would be placed on the durability of goods, recycling, and the restriction of effluents (which often contain "resources" not now economically recoverable). Environmental deterioration from the processes of resource extraction and transport would be reduced, as would that resulting from manufacturing resources into finished goods. Less energy is usually required to recycle materials than to start anew from basic resources. And depletion quotas on fossil fuels and fissionable materials would encourage the frugal use of energy.

Limiting the amount of energy available would, of course, also tend to limit the weight and number of automobiles, encourage' the use of mass transit, and promote the substitution of efficient high-speed trains for energetically wasteful short- and medium-haul jet airplanes. As Daly notes, a basic system of depletion quotas would have to be supplemented to some degree with such devices as taxes on effluents, but we agree with him that operating at the resource rather than the rubbish end of the system is fundamentally the better approach. It requires controls at many fewer points and thus would be simpler to institute, because it tackles the system where the materials are still concentrated rather than dispersed.

One of the most difficult problems in implementing the Daly system would be dealing with imports. Obviously, quotas would have to be established on imported raw materials, or the primary result of the system would be merely to shift pressure from U.S. resources to the

resources of the rest of the world. If American manufacturers alone were strictly rationed, there would surely be an upsurge in manufactured imports. Restrictions therefore would have to be placed on the import of manufactured goods, perhaps based on their "resource content." Those restrictions might best be put only on imports from other developed countries to encourage them to establish depletion quotas also. Restrictions could be omitted for certain manufactured goods from less developed countries wherever it seemed that access to United States markets would be a genuine economic help to the exporter.

Another suggestion for a government system that could be employed to limit throughput has been put forward by two ecologists (described in Box 14-3). It is a more complex system than Daly's, but has the big advantage of making the public aware of the environmental impact of human activities.

Daly claims that cornucopians should make no objection to schemes that limit resource depletion, for they are eternally assuring us that technological progress (such as substitutions for depleted resources) would be encouraged by rising resource prices, and that such advances would make resource supplies virtually infinite. [103] Since depletion quotas would increase the price incentives, they could be viewed as a test of the faith of the technological optimists -- a test that would simultaneously conserve our resource heritage in case not enough technological rabbits appear from the hat.

---

[102] The stationary state economy. See also his *Toward a steady-state economy*, for expansion of these ideas.

[103] See, for example, H. E. Goeller and A. Weinberg, *The age of substitutability*.

BOX 14-3 A Novel Scheme for Limiting Environmental Deterioration

Two Australian ecologists, Walter E. Westman and Roger M. Gifford, have put forth a novel suggestion for maintaining the quality of the environment at any level desired by society. [*] They propose establishing a money-independent "price" on every activity that has a clear environmental impact. The basic nonmonetary unit would be the natural resource unit (NRU). NRUs would be distributed equally among individuals and by special means to business firms, government entities, and nonprofit organizations.

The overall level of environmental impact would be regulated by government establishment of both the total yearly allocation of NRUs and the price in NRUs of every good, service, and activity of environmental significance. This would lead in effect to a "rationing" of rights to pollute, destroy habitats, add to population pressure, or extract natural resources.

The advantages of such a system are numerous. Open, rather than covert, decisions on the quality of the environment would be made. Since NRUs would not be transferable, the system would be equitable -- the rich would not be allowed greater per-capita impact than the poor. Individuals, however, would be able to accumulate NRUs throughout their lives and could determine how to spend them free of arbitrary government decision-making. It might be possible, for instance, for

an individual to have a second child or to fly a light aircraft 100 hours per year, but not both. Or one might decide to have an air-conditioned house, but if so, an overseas vacation might be possible only once every ten years. Instead of direct constraints being placed by society on activities, each person's life-style would be partially determined by a series of environmental trade-offs of his or her own choosing.

On the debit side would be the enormous bureaucratic problem of setting up the equivalent of a second monetary system, the great problem of assigning reasonable values to goods and activities, and the inevitable corruption and scheming that institution of such a plan would induce. Its authors present a most interesting discussion of its details and offer it in the full knowledge that it is not politically feasible at present. But it is hard to disagree with one of their major conclusions: "Although involving more planning and more governmental regulation than is currently deemed feasible or acceptable, we believe the mechanism would lead to less restriction of personal freedom in a steadystate society than would the current trend toward unsystematic imposition of governmental regulations."

Daly summarized his distributive and throughputlimiting proposals as follows:

In spite of their somewhat radical implications, these proposals are based on impeccably respectable conservative premises: private property and the free market. If private property is good, then everyone should share in it; and, making allowances for a range of legitimate inequality, no one should be allowed to hog too much of it, lest it become the instrument of exploitation rather than the barrier to exploitation that was its classical justification. Even orthodox economic theory has long recognized that the market fails to deal adequately with depletion, pollution, and distribution. These proposals supplement the market at its weak points, allowing it to allocate resources within imposed ethical and ecological limits. [104]

Much additional effort by economists and others will be required to work out details of the changes required in order to minimize throughput in the economic system. One further step, however, is already clear. Both before and after depletion quotas are established, ways must be found to control advertising. Advertising plays a key role in promoting growthmania in the DCs. In those nations the basic human needs for food, clothing, shelter, medical care, and education are being met for perhaps 90 percent of the populations. In order to keep those economies growing, therefore, new "needs" must be created. E. F. Schumacher has written, "The cultivation

---

*Environmental impact: Controlling the overall level.

[104]1975 testimony, p. 12.

and expansion of needs is the antithesis of wisdom. It is also the antithesis of freedom and peace. Every increase of needs tends to increase one's dependence on outside forces over which one cannot have control, and therefore creates existential fear. Only by a reduction of needs can one promote a genuine reduction in those tensions which are the ultimate cause of strife and war." [105]

The employment problem. Redirecting production into more useful channels and reducing the throughput associated with production will entail considerable retraining and temporary unemployment in the work force. These problems will be all the more difficult in the United States because of the unemployment problem that already exists. The 4 to 10 percent unemployment figures commonly quoted as the economy cycles between boom and recession do not reveal the true seriousness of the problem. First of all, this overt unemployment is very unevenly distributed in the population. Racial minorities, young workers, women, and, above all, young minority workers suffer disproportionately. The pressure of unemployment at the younger end of the labor pool is probably a major reason that American society has been so rigid about retirement around the age of 65. Many talented people are removed from the labor force even though they may still be capable of ten years or more of productive work and do not wish to be "put out to pasture." The enforced separation of older people from their economic lives also clearly contributes to their general problems.

Added to these components of the employment picture is disguised unemployment: people doing jobs that are either unnecessary or detrimental to society, or both. Anyone familiar with government, big business, universities, the military, or any large bureaucracy, knows how many people are just doing busywork or pushing paper. When those people are combined with workers who are engaged in such fundamentally counterproductive activities as building freeways, producing oversized cars and unneeded appliances, devising deceptive advertising, or manufacturing superfluous weapons systems, the number of people who are unemployed, underemployed, or misemployed is seen to make up a substantial portion of the work force.

Of course, the whole employment problem would be badly aggravated if society attempted to discontinue too abruptly those jobs that are unnecessary or socially and environmentally destructive. Maintaining some of those activities is probably necessary in the short run while changes in employment patterns are worked out. But now is the time to start planning and maneuvering to phase out both disguised unemployment and destructive products without damaging society and without creating enormous levels of overt unemployment.

The transition should be greatly assisted by the obvious potential for expanded employment in services such as health care and education (including adult education); in developing energetically efficient transportation systems for people and freight; in perfecting and deploying solar and other environmentally desirable energy technologies; in recycling and pollution-control industries; in environmental improvement activities such as reclamation of strip-mined land, reforestation, and the construction of urban parks; in converting the food production system to more wholesome, less wasteful and energy-consumptive practices; and in the development, production, and distribution of better contraceptives. [106] Ile transition should also be eased somewhat because the numbers of new young job-seekers will begin to decline after 1980, because of the smaller number of births in the United States in the 1960s compared to the 1950s. And, if the trend of past decades in which workers have been increasingly replaced by fuel-burning machinery is reversed, the result obviously will be more jobs.

In the longer term, even with greater use of labor instead of machines in some areas of the economy, the solution to the employment problem may well require a reduction in the amount of work done by each worker in order to create more jobs. Gradually shortening the work week

(ultimately to twenty-five hours or less) or decreasing the number of work weeks per year (companies could have different spring-summer and fall-winter shifts) would accomplish this. There would be more time for leisure, which might be better enjoyed by a more educated population. There would also be more time for people both to obtain that education and to put it to good

[105]*Small is beautiful* p. 31.
[106]See, for example, Patrick Heffernan, *Jobs and the environment*.

use participating in running society (see *"Education"*). There should be few but positive consequences from such a reduction in working time. Pay might have to be reduced, but so would many expenses if material goods were built to endure and there were no longer social pressures to consume for the sake of consuming. If people could be diverted from the high-speed, mechanized forms of leisure activity now promoted by advertising, the pace of life would undoubtedly slow down, with attendant psychological and physical benefits. If a stable economic system could be achieved, life would indeed by different from -- and conceivably much improved over -- what it is today.

Economics and pesticides: a case history of environmental politics. The profound changes necessary to save the environment and society will not be made easily, however. Powerful opposition can be expected from economic interests. Such opposition has long been mounted by the petrochemical industry, whose behavior foreshadowed that of other industries. It is worthwhile to examine this behavior in some detail at this point as an example of the kinds of barriers that may obstruct any attempts to establish a spaceman economy in the United States.

The giant petrochemical industry has applied constant political pressure (through friends in Congress and such agencies as the USDA) and has resorted to outright lies about the safety of pesticides in order to avoid regulation, particularly since the publication in 1962 of Rachel Carson 's book, *Silent spring*, which was addressed to the public at large. The industry has attempted to discredit responsible scientists who have nothing to sell, but who oppose modern patterns of pesticide usage because they have learned through careful and patient study that DDT and related pesticides are not mere killers of insects, but threaten the capacity of Earth to support human life. Desperately worried biologists have attempted, through public education and by going to court, to keep more of these poisons from entering the environment, and concerned conservationists have done what they could. But until 1969 the petrochemical industry was almost completely successful in forestalling any effective regulation of its activities. Since the Wisconsin hearings on DDT in that year, the industry has been losing battles, but not gracefully.

The industry's early tactics were typified by an editorial that appeared in the journal *Farm chemicals* (January 1968), which not only labeled every biologist critical of current pesticide practice as a member of a "cult" and a "professional agitator," but also claimed that "scientists themselves literally ostracized Rachel Carson, and they will come to grips with this eroding force within their own ranks. Of course, it is not unusual that the character of the scientific community is changing. It may be a sign of the times. The age of opportunism!" This editorial appeared four

years after Rachel Carson's death, yet the ghost of this remarkably sensitive and extremely capable marine biologist apparently still haunted those whose products she had found were dangerously polluting the environment.

Unquestionably, some chemists and entomologists attempted to discredit Rachel Carson. Most of those who did, however, were either employed by the petrochemical industry or were too narrowly trained (as many entomologists still are) to appreciate the dangers in the use of such powerful chemicals. Scientists in other disciplines disagreed with her too, but for the wrong reasons: some argued that she was speaking outside her field of expertise; others charged her with emotionalism. Thousands of biologists, however, admired her tremendously for her breadth of view and for awakening the general public to the hazards posed by the use of dangerous chemicals in attempts to increase the production of food.

It is true that there were a few factual errors in *Silent spring*, but in many ways Rachel Carson *underestimated* the hazards of DDT and certain other chlorinated hydrocarbons. Nevertheless, she succeeded in awakening the public -- and did so in a way that a more technical and highly documented book like Robert L. Rudd's *Pesticides and the living landscape* could not. Rudd, a zoologist, came to many of the same conclusions that were presented in *Silent spring*, but because his book was not addressed to the general public it did not engender the level of attack that was directed toward the Carson book. In our opinion, no biologist has made a greater contribution to humanity in this century than Rachel Carson. And recent events and government decisions

have fully justified her position.

The petrochemical industry is now on the defensive because, as we described earlier in this chapter, scientists and other citizens have discovered that there are legal remedies against environmental degradation and health hazards and have been using them.

It seems unlikely that the reaction of the industry was based on the DDT or chlorinated hydrocarbon issue alone. A more likely reason was apprehension about the precedents that would be set if any or all of those chemicals were banned or restricted in use. The industry would prefer to account primarily to the friendly and compliant USDA, not to the EPA or to groups of scientists who are worried about the ecological effects and long-term dangers to human well-being caused by their activities.

Soon after the Environmental Protection Agency was created in 1970, it was given responsibility for the registration and regulation of pesticides. Litigation by the Environmental Defense Fund produced a court order early in 1971 for EPA to issue public notices of cancellation of registration of DDT and to review DDT for suspension. Cancellation stops sales after thirty days, provided that the manufacturers do not appeal, a process that can go on for years. Suspension, on the other hand, takes effect at once, even as appeal proceeds. The notices of cancellation for DDT, as well as aldrin, dieldrin, mirex, and the herbicide 2,4,5-T were, of course, appealed.

After lengthy hearings, EPA banned DDT for almost all uses in 1972. It found that DDT "posed an unacceptable risk to man and the environment." [107] Restrictions were also placed on the use of mirex, a pesticide mainly used against the fire ant (Appendix 4). The proceedings against 2,4,5-T were confused by the discovery that tetrachlorodioxin (TCDD) impurities were the major toxic threat from that herbicide.

Between 1972 and 1974 restrictions were placed on aldrin and dieldrin, and in October 1974 an immediately effective ban was placed on their production. EPA administrator Russell E. Train's decision was made because those compounds represented an "imminent hazard" [108] because of their capacity to induce tumors in mice (indicating a direction in the EPA similar to the Delaney amendment's zero tolerance for food additives found carcinogenic in test animals, described in Chapter 10). In July 1975 two other chlorinated hydrocarbons, chlordane and heptachlor, were also banned because of their carcinogenicity in laboratory tests. All of these bans are under appeal as this is written, but the trend toward much more careful regulation of pesticides had been clearly established a decade after Rachel Carson's death from cancer in 1964, and the EPA was showing signs of increasing toughness.

In 1972 the old Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) was amended by the Federal Environmental Pesticide Control Act (FEPCA), expanding the EPA's authority to classify pesticides for general or restricted use, regulate the way they are used, and specify labeling -- authority that was quickly employed to improve record-keeping on amounts and disposition of all pesticides produced. In October 1974 the EPA announced proposed regulations for registering new pesticides and reregistering those already on the market. In a critical provision, those regulations established a "presumption against new or continued registration of any pesticide with extremely high acute toxicity characteristics *or which produces in laboratory or field situations any evidence of oncogenicity [tumor induction], teratogenicity, or multitest evidence of mutagenicity. . . .*" [109]

The presumption could be rebutted, but the burden of proof would be on the company applying for registration. To say the least, the pesticide industry is "concerned" about the tough new regulations -- and, if only from an economic point of view, they should be, since there is strong evidence that the cost of developing new products and keeping them registered is increasing rapidly. [110]

A comprehensive study of the problems of pestcontrol by a committee of the National Academy of Sciences concluded that regulation could be improved, but that provided little comfort to the petrochemical industry. The study found that considerations entirely

[107] CEQ *Environmental Quality -- 1972*.
[108] L. J. Carter, "Controversy over new pesticide regulations".
[109] Quoted by Carter (his emphasis).
[110] National Academy of Sciences, *Study on problems of pest control*.

within the agricultural sector -- namely, the declining efficacy of pesticides with the development of resistance in pests -- demanded greater attention to alternative methods of pest control. The committee was especially concerned with the impact of regulation on the development of new technologies to replace the conventional broad-spectrum chemicals that have dominated the pestcontrol scene since 1950. It is clear, of course, that the required technologies are unlikely to be generated within the chemical industry. The NAS report went on to point out:

The products produced by the chemical industry appear admirably to meet the economic goals that we assume dominate the decision-making processes in private industry. Unfortunately, the sole example of overlap between the properties desired by the industry and those of the most promising alternatives would seem to be the observation that the industry favors short persistence over long by a wide margin. Conversely, however, industry favors a broad spectrum of biological activity over a narrow spectrum by almost the same margin. [111]

In short, a compound that must be repeatedly applied, that kills natural enemies, and produces rapid evolution of resistance is preferred by pesticide manufacturers -merely because, in the process of not working, it can be recommended in ever-increasing doses and eventually can be replaced by another ecological sledgehammer marketed by the same industry. Pest-control techniques that were truly effective, of course, would be a disaster for the pesticide industry.

Implementation of one regulatory recommendation of the NAS study, that the availability of alternatives should influence registration judgements, would be another serious blow for the industry, as well as a major step toward protecting humanity from its activities. Tougher regulations quite likely would cause some decline in traditional firms involved in manufacturing pesticides. Fortunately, as noted in Chapter 11, ecologically sound pest management (which would include sparing use of chemicals integrated with other techniques) would be more labor-intensive than the present broadcast-spray system. At least in theory, then, a transition to such management could be accomplished with a net gain of jobs in the economy, although many individuals would certainly have to be retrained.

Economics versus environmental reality. Defensive reactions have also come from other industries whose activities contribute heavily to pollution. Representatives of the inorganic-nitrogen-fertilizer industry have given extensive testimony before Congress, most of which confirmed the belief of many biologists that the industry just cannot (or does not want to) grasp the dimensions of the problems that result from failure to maintain an adequate supply of humus in the soil. Manufacturers of fluorocarbons and aerosol cans have vigorously lobbied against restrictive legislation. Makers of nonreturnable containers and poisonous food additives have fought to continue marketing their products. The list is both interminable and understandable; no person or corporation likes to see income or economic survival threatened.

It is most difficult to protect the environment when economists, industries, and government agencies team up to wreak havoc, as they did, in effect, in the case of the supersonic transport. Building and marketing a commercial SST was "justified" in the United States largely on the grounds that it was needed economically to protect the balance of payments. President Richard M. Nixon, in endorsing the nation's SST program in 1969, stated, "I want the United States to continue to lead the world in air transport." The economic penalties that would be incurred from

damage caused by sonic booms were probably not included in the administration's consideration of whether to proceed with the project, nor were the psychological and emotional damages people would suffer, nor the possible effects on the world's climate (which themselves might cause heavy economic damage) from the operation of these high-altitude jets. Indeed, even the lethal possibility of reducing Earth's ozone shield took second place to the balance of payments.

Fortunately, a combination of factors, including intensive lobbying on the adverse side effects of the SST by environmental organizations and testimony by several distinguished economists that it was an economic boon-

[111] Ibid., vol. 1, p. 139.

doggle, convinced Congress that the SST's disadvantages outweighed its very questionable advantages, and the U.S. program was killed in 1971.

In 1975 the debate began anew when rights to land in the United States were requested for the AngloFrench SST, Concorde. The issue is still in doubt, but several things are apparent -- the Concorde is extremely noisy, fuel-inefficient, and probably uneconomical. If it remains in service, it will be as a monument to government stupidity and the momentum of technological circuses.

Government Planning

The fragmentation of responsibility among government agencies in the United States makes a reasonable response to problems extremely difficult and planning to avert them virtually impossible. The lack of overall control of environmental matters and the virtual impossibility of dealing with problems in any coordinated way are illustrated by the area of urban affairs, aspects of which now come under the jurisdictions of the Department of Housing and Urban Development, the Department of Health, Education and Welfare, as well as the Departments of Labor, Commerce, Interior, Justice, and Transportation, to name just the major ones. It is clear that the executive branch of the federal government badly needs reorganizing.

Such coordinated planning as takes place in the federal government is largely confined to the preparation and review of the annual federal budget. It is fair to say that the time horizons considered in this process are typically short and the emphasis on conventional economic indicators heavy. Resource and environmental matters accordingly receive less attention than they deserve. [111a]

Some detailed suggestions on reforming the political structure of the United States to make it more responsive to the requirements of the population-resource-environment situation may be found in the book *Ark* II. [112] We discuss only one such reform here: the institutionalization of government planning.

The Center for the Study of Democratic Institutions has an ongoing project under the direction of R. G. Tugwell, designed to produce a modern constitution for the United States. The proposed constitution, now in its thirty-third draft, deserves wide circulation and study. One of the features of the Tugwell constitution is a planning branch of the government, with the mission of doing long-range planning. As should be apparent from the preceding discussion, without planning we believe there is little chance of saving civilization from a downward spiral of deepening social and environmental disruptions and political conflicts. Human societies have shown little aptitude for planning so far, but it is a skill that must soon be developed. [112a]

A private organization, California Tomorrow, sponsored a group of planners who produced a document that might serve as a preliminary model for the kind of planning that can be done. *The California tomorrow plan: A first sketch* presents a skeletal plan for the future of the state of California. [113] It describes "California zero," the California of today, and two alternative futures: California I is a "current-trends-continue" projection; California II is a projection in which various alternative courses of action are followed.

The plan considers twenty-two major problem areas, including population growth and various kinds of environmental deterioration, and looks at both the causes of the problems and policies to ameliorate them. California I is compared with California II, and suggestions for phasing into the California II projection are given. The details of the plan need not concern us here, but the subjects of concern in the plan are roughly those of this book. What is encouraging is that a private organization could put together a comprehensive vision of the future of one of the largest political entities in the world, proving that intelligent, broad-spectrum planning can be done.

[111a] A sense of the planning inputs to and implications of the federal budgeting process is conveyed in the series of volumes, *Setting national priorities*, published annually by the Brookings Institution since 1970. The 1976 volume, edited by Henry Owen and Charles L. Schultze, takes a longer-range perspective (10 years) on issues raised by the budget, and examines the problems of coordinated long-range planning in a government of divided powers.

[112] Pirages and Ehrlich.

[112a] A series of important books on the tools and prospects for comprehensive governmental planning appeared in 1976 and 1977 under the authorship of social scientist and modeler Peter W. House and colleagues: House, *The quest for completeness*; House and Williams, *The carrying capacity of a nation*; House and McLeod, *Large scale models for policy evaluation*; House, *Trading-off environment economics, and energy*.

[113] Alfred Heller, ed., *The California tomorrow plan*

The next question is, how can "USA Zero" be started toward "USA II"? It may well be necessary to form a new political party founded on the principles of population control, environmental quality, a stabilized economy, and dedication to careful long-range planning. Such a party should be national and international in its orientation, rather than basing its power on parochial issues as the current parties do. In 1854 the Republican party was created de novo, founded on the platform of opposition to the extension of slavery. It seems probable that in the 1980s and 1990s

the environmental issue will become even more prominent than the slavery issue was in the 1850s, and a powerful new ecology party might be established, as has occurred in several other countries. It could, indeed, grow out of such political organizations as Zero Population Growth and Friends of the Earth.

Obviously, such changes as those briefly proposed above will threaten not only numerous politicians of both major parties, but many economic institutions and practices. They are likely to be opposed by vast segments of the industrial state: by much of the oil and petrochemical industry, the steel industry, the automobile industry, the nuclear power industry, the construction industry, and by some labor unions, land developers, the Army Corps of Engineers, the USDA, the Nuclear Regulatory Commission, and the chambers of commerce, to name only a few.

Even a cursory knowledge of the pervasiveness of and the degree of political control by these interests leads to the conclusion that the necessary changes in attitudes and behavior are extremely unlikely to occur among the individuals and organizations where it would be most helpful. But what is at stake is survival of a society and a way of life. If these are to be preserved in recognizable form, cooperation of all elements of society, regardless of personal interests, will be required. Some social scientists believe such cooperation can be obtained by the systematic application of social and political sanctions. [113a] We tend to agree, but doubt that even sanctions will work unless there is also a common goal -- a realistic view of a desirable and attainable future -- that all can strive toward.

SOME TARGETS FOR EARLY CHANGE

Institutions are shaped by issues, and issues in turn are shaped and evolve in response to the character of the institutions that identify and grapple with them. Accordingly, our discussion of American institutions so far has been framed in the context of the broad issues in population and environment that we believe are central to the human predicament. It is useful now to add to the discussion some rather more specific problem areas-energy policy, transportation and communications, and land use -- which need early attention, which will test the ability of institutional change to redirect technology and social energies in pursuit of saner ends, and which, in being grappled with, may serve to reshape further the institutions themselves. Along with population policy and pollution control, which have already received detailed attention in this and the preceding chapters, we view these problems as high-priority targets for early change.

Energy Policy

Who should make energy policy? How should it be carried out? What should be its goals? These are the principal questions on the policy side of energy, and they are interdependent. As unfortunately sometimes is forgotten, it is fruitless to try to answer the first two questions without already having some semblance of an answer for the third.

The United States had an energy policy during the first two-thirds of the twentieth century, but it was rarely articulated in public. In any event, the public was not paying much attention. The policy was the result of the goals of two groups--a few interested politicians and their appointees, whose goal was to see that energy was made available as cheaply as possible to meet whatever

demand might materialize, and the owners and operators of energy companies (oil companies, coal companies, energy-equipment manufacturers, electric utilities, and so on), whose goal was to expand their businesses and their profits as rapidly as possible. The goals of the two groups coincided nicely.

That the interests of private enterprise and of public

[113a] L. D. Nelson and J. A. Honnold, *Planning for resource scarcity*.

policy coincide is not necessarily a bad thing. As Adam Smith expounded the idea in his famous metaphor of the invisible hand, this is the way a free-market economy full of entrepreneurs is supposed to work. Unfortunately, the history of U.S. energy policy is one of the most telling available examples of what can go wrong with this ideal situation: the consolidation of economic interests into oligopoly and monopoly; the tightening influence of the economic interests over the policy-makers and regulators, and indeed the infiltration of the latter by the former; the resulting vigorous pursuit of policies that still serve private interests but have long since lost their relevance to the public interest.

This complicated set of issues has been the focus of many analyses much more extensive than we can provide here. [114] What follows is a brief overview of some of the most important topics: the character of the U.S. energy industry, government activity in energy, and energy prices and the poor. International aspects of energy policy are considered in Chapter 15.

U.S. energy industry. The energy industry is an important sector of the U.S. economy by any measure: according to one tabulation, it accounts for 3 percent of the total employment, 4 percent of the national income, and 27 percent of the annual business investment in new plants and equipment. [115] A different way of counting, which includes taxes and other items missed in the figures just given, is to add up all the money spent on energy by consumers. Such a tabulation must include both direct purchases (gasoline, electricity, natural gas, heating oil) and indirect purchases of energy (for example, the fraction of an airline ticket's price that pays for jet fuel, the part of the price of an automobile that pays for the energy needed to build it, the energy to run the hair drier at the beauty parlor, and so forth). The total

computed this way was around 10 percent of the gross national product at pre-embargo (1973) energy prices.

The greatest concentration of economic and political power in the energy industry is found in the large oil companies. Ten of the top twenty companies on *Fortune* magazine's 1975 list of the largest industrial corporations in the United States were oil companies, and the assets of those ten alone topped $154 billion. Their 1974 sales were $116 billion. [116] Those companies have become large both by vertical integration and by diversification. The first term means that a single company is involved in many stages of processing an energy source--for example, exploration, production, refining, marketing. Diversification refers to involvement of a single company with several different resources--for example, oil, coal, uranium, oil shale. (Naturally, diversification can go beyond energy resources--some oil companies own movie theaters, for example.) A glance at Table 14-1 reveals that the major oil companies are really energy companies, as all of them are involved with three or more different resources.

As big as the major energy companies are, the concentration of the energy business in the few largest organizations does not quite qualify for the label *anticompetitive* under the usual rule of thumb, which is that 70 percent of the business be concentrated in the largest eight firms. [117] The degree of concentration in various sectors of the U.S. energy industry is shown in Table

[114] Especially recommended as introductions to the subject are: David Freeman et al, *A time to choose: The report of the Energy Policy Project of the Ford Foundation*, chapters 5-7, 9-11; J. Steinhart and C. Steinhart, *Energy*, chapters 13 and 14; N. Medvin, *The energy cartel*; *Resources for the Future, U.S. energy policies: An agenda for research*.

[115] David Freeman et al., *A time to choose*, p. 142. Included are production and processing of coal, oil, and natural gas, gas and electric utilities, pipeline transport, and wholesale and retail trade. Not included are manufacturers of energy-handling equipment, such as electricity generators and nuclear reactors.

[116] Fortune directory of the 500 largest industrial corporations, *Fortune*, vol. 91, no. 5 (May 1975), pp. 210-211.

14-2. The effective degree of concentration is probably higher than the figures reflect, however, because of the large number of joint ventures linking the major companies in collaborative enterprises. These include jointly owned or operated oil fields, pipelines, refineries, and a bewildering variety of other arrangements. Among the ten or fifteen largest oil companies, almost all of the possible two-company combinations in joint ventures are actually in existence. [118]

The political power of the major energy companies in practice is reflected in the special treatment by the government they have gained and largely preserved for themselves in the forms of the depletion allowance, foreign tax credits, and other tax dodges. [118a] (The depletion allowance for all but the smallest producers was at last repealed in 1975.) Between 1962 and 1971 the five largest U.S. oil companies paid an average of 5.2 percent income tax on their profits, compared to an average corporate income tax for all industries of about 42 percent. The difference could be regarded as a raid on the U.S. Treasury by those five companies in the amount of about $17 billion. [119] (These five companies were all in the top ten U.S. corporations in profitability in 1976. Their after-tax profits totalled $6.2 billion. [119a])

It may be argued, of course, that developing and marketing energy resources is an increasingly complicated and expensive business that only very large and financially vigorous corporations can handle. Indeed, this is precisely what the energy companies do argue. Yet it is not entirely clear what the American people as a whole gain by leaving those very profitable and also very crucial activities in the hands of private enterprise. Increasingly, the same corporations that swear by the free-market system in some respects have shown themselves more than willing to abandon it selectively, campaigning for all manner of special subsidies, tax incentives, and privileges, while expecting the government to undertake the riskiest and most difficult parts of the energy enterprise. Thus the federal government finds itself providing most of the liability insurance for nuclear reactors, trying (without much success as of 1976) to persuade private industry to get into the uraniumenrichment business, underwriting most of the cost of a demonstration breeder reactor for the utilities, paying to bring the technology of sulfur control for coal and oil to a state of development deemed economically viable by the utilities, and so on.

On the other hand, the idea of letting the government take over the energy business entirely is not particularly appetizing. The experiences of other nations where the energy industry has been

nationalized shows that this is no guarantee against bungling and exploitation, as does the U.S. experience with government enterprises in other fields. At the same time, it seems clear that the goals of the energy companies have become increasingly removed from the public interest in the 1970s. More energy for its own sake (or for profit's sake) can no longer serve as the goal of national energy policy, and it is apparent that much tighter control over the energy industry by government is the minimum prescription for steering away from this outmoded view.

Government's role. The response of government to the growing complexity of energy issues over the past few decades has been piecemeal and uncoordinated. Each emerging set of problems, it seems, has led to creation of a new agency or assignment of responsibility to an existing one, without regard for the way pieces of the energy problem interact with each other. The result is overlapping jurisdiction in some cases--in which conflicts arise among federal, state and local governmental entities--and no jurisdiction at all in others. Some of the principal federal agencies involved in energy are listed in Box 14-4, along with synopses of their responsibilities that suggest some of the potential conflicts and ambiguities. Operating sometimes in collaboration with,

BOX 14-4 Some Federal Agencies Involved in Energy

Council on Environmental Quality (CEQ)

- Consults with other federal agencies on environmental impacts of their actions
- Recieves and evaluates environmental impact statements on energy facilities

Energy Research and Development Administration (ERDA)

- Develops and demonstrates new sources of energy supply
- Analyzes and encourages energy conservation
- Makes forecasts of energy needs and proposes strategies to meet them
- Operates certain energy facilities (such as uranium-enrichment plants)

Environmental Protection Agency (EPA)

- Sets standards for pollutants from energy facilities
- Regulates leasing of energy resources (such as oil drilling, coal mining) on federal lands, including offshore
- Maintains statistics on reserves and production of mineral energy resources
- Produces and markets electric power through four regional administrations (Bonneville, Alaska, Southwest, Southeast)

Federal Energy Administration (FEA)

- Collects and verifies information about availability of energy to consumers
- Regulates the mix of products from refineries
- Allocates energy supplies in times of shortage
- Makes forecasts and devices strategies

Federal Power Commission (FPC)

BOX 14-4 Some Federal Agencies Involved in Energy

- Devises and enforces standards for air and water quality, bearing on operation of power plants and automobiles

Department of Commerce (DOC)

- Devises and implements programs and standards for industrial energy conservation

Department of Housing and Urban Development (HUD)

- Devises and implements standards for energy conservation in buildings

Department of the Interior (DOI)

- Controls energy development (for example, Controls prices and standards of service for sales of electricity and natural gas across state lines
- Licenses hydropower facilities on navigable waterways

Interstate Commerce Commission (ICC)

- Regulates interstate oil and coal-slurry pipelines

Nuclear Regulatory Commission (NRC)

- Devises and enforces standards for safety of nuclear-energy facilities

Securities and Exchange Commission (SEC)

- Regulates management practices of electric utilities

sometimes at odds with these agencies is a host of congressional committees, themselves engaged in almost continuous jockeying with each other for jurisdiction and influence.

In early 1977 President Carter proposed a sweeping reorganization of energy-related functions in the Executive Branch, centered around a new Department of Energy equal in status to Commerce, Interior, Treasury, and so on. Upon approval by Congress, the Department of Energy will replace the Energy Research and Development Administration, the Federal Power Commission, as well as assuming most of the energy-related responsibilities of the Department of Interior, the Department of Commerce, the Department of Housing and Urban Development, the Interstate Commerce Commission, and the Securities and Exchange Commission. Two new administrations would be created within the Department: the Energy Information Administration, collecting and distributing information about energy supplies and uses, and the Energy Regulatory Commission, covering economic regulation only. The Nuclear Regulatory Commission, the Environmental Protection Agency, and the Council on Environmental Quality would retain their powers as listed in Box 14-4.

The confusion in Washington (which one may hope the Carter reorganization will reduce) is compounded, of course, by the existence of public utilities commissions in forty-six of the fifty states, with widely varying responsibilities in the energy field. About half of them control both public and investor-owned utilities (electricity and

natural gas, plus nonenergy activities); the other half control only the investor-owned utilities. Most set the rates charged for electricity and gas, to protect the consumer from the monopoly that the nature of distribution systems for gas and electricity makes almost inevitable. They are

also generally responsible for assuring the safety of systems under their jurisdiction, one of several overlaps with other agencies.

Government action in the energy field is not only encumbered by this enormous organizational complexity, but it has often been enfeebled as well by internal conflicts of interest. These have arisen from the standard problem of infiltration of regulatory agencies by committed representatives of the regulated organizations, and also sometimes from the incorporation of promotional and regulatory functions within the same agencies. Perhaps the most visible example of the pitfalls of the latter situation was the Atomic Energy Commission, which from its creation in 1946 was empowered both to regulate and to promote the peaceful and military applications of nuclear energy. Some of the difficulties that nuclear fission as an energy source faces in the late 1970s can be attributed to mistakes that arose from this inherent conflict and from the cozy relationship that evolved between the AEC and its supposed congressional watchdog, the Joint Committee on Atomic Energy, (JCAE). [120]

The AEC-JCAE combination for many years was the most active and visible agency connected with energy in Washington, and its vigorous promotion of nuclear fission to the near-exclusion of research on other energy sources left the United States in the 1970s with far fewer energy options than it could and should have had. The AEC was split in late 1974 into the Nuclear Regulatory Commission, on the one hand, and several divisions of the Energy Research and Development Administration on the other (see Box 14-4). The JCAE was stripped of its power in a Congressional committee reorganization in early 1977.

Energy prices and the poor. If it is obvious that energy in the United States has been underpriced, encouraging overexploitation and waste, it is equally apparent that sharp price increases cause a disproportionate burden on the poor. The poor spend a larger fraction of their incomes on direct energy purchases than do higher-income groups, they are less able to cut back on energy consumption because a larger part of their consumption is for essential rather than discretionary uses, and they are less able to invest money in insulation and other improvements that will reduce energy expenditures in the long run. [121]

Increases in energy prices are not *quite* as regressive as they seem at first glance, however, because total energy expenditures (for direct purchases plus the "indirect" energy embodied in other goods and services) increase almost in direct proportion to income. [122] Even so, the plight of the poor requires that special measures be taken to reduce the impact of higher energy prices on them. Such measures should include changing the rate structure for purchases of electricity and natural gas, so that small users pay less per unit of energy rather than more (compared with large users), as is now generally the case. Subsidies for the purchase of insulation and similar improvements could easily be paid for out of increased taxes on the profits of energy companies. It would not be difficult to design an energy tax and rebate system that actually served as an income redistribution device favoring the poor while discouraging heavy energy consumption in higher-income groups.

In short, the special problems of the poor must be taken into account as energy prices rise, and they can be. Indeed, the nation would have to face up to the problems of the poor whether energy prices were rising or not. It would be doubly absurd if the government were to take the position,

having failed to deal adequately with the problem of poverty directly, that its energy policy must revolve around holding energy prices low for everyone in order to deal with poverty indirectly. At the same time, there is no reason whatever that higher prices for energy, which are needed to help promote conservation and to pay for ameliorating energy's environmental damages,

[120]Good critical histories are R. Lewis, *The nuclear power rebellion: Citizens versus the atomic industrial establishment*; P. Metzger, *The atomic establishment*.

[121]According to Freeman et al., chapter 5, poor Americans spent 15 percent of their income on natural gas, electricity, and gasoline in the early 1970s, compared to 7 percent, 6 percent, and 4 percent for the lower middle class, upper middle class, and the well-off segments of the population.

[122]R. Herendeen, *Energy and affluence*.

must mean higher profits for the energy companies. Preventing this is a straightforward matter of tax policy.

Directions for a rational energy policy. The main questions that energy policy must confront can be summarized: (1) How much energy should be supplied? (2) With what technologies should it be supplied? (3) Who should pay the associated costs? At issue under the first question are the costs and benefits to society of various levels of energy consumption and various rates of change in those levels (growth or decline). The second question -- which should be viewed not as a search for the ideal energy source but as a search for the least undesirable mixture of sources -- is important regardless of the answer to the first; a stabilized or even a reduced level of energy use would not absolve society from making difficult choices about how best to supply that level. Similarly, the third question -- involving how prices, taxes, and regulation are employed to distribute the direct and indirect costs of energy use -- is crucial no matter how the first two questions are answered.

Still, the three questions are far from independent. If the answer to the question "How much?" is a great deal, the range of choice under "What technology?" diminishes; society may have to choose all the options at once, at great expense. And the greater the costs, the trickier is the question "Who pays?"

On the question of how much should be supplied, our view is that the United States is threatened far more by the hazards of too much energy, too soon, than by the hazards of too little, too late. That the contrary view is so widely held seems to be the result of two factors: (1) The economic, environmental, and social costs of today's level of energy use, and of rapid growth in this level, have been seriously underestimated by most observers. (2) The economic and social costs of slower growth have been just as seriously overestimated. The underpinnings for these assertions are found in Chapters 8, 10, and 11. [122a] We reiterate here in capsule form the relevant conclusions that we draw from that material. [122b]

Rapid growth in energy use fosters expensive mistakes. Especially where the existing level of energy use is already high, rapid growth forces exploitation of highcost energy sources as well as

low-cost ones, it strains available supplies of investment capital, and it encourages gambles on inadequately tested technologies. The pressure of growth favors streamlining of assessment and licensing processes, further enlarging the probability that some of the gambles will fail -- at great economic, environmental, or social cost.

Even at slower growth rates, increases in energy use may do more harm than good. While the productive application of energy fosters prosperity through the operation of the economic system, the environmental and social effects of the same energy flows undermine prosperity by means of direct damage to health, property, and human values, and by disrupting "public-service" functions of natural systems. Clearly, the benefits to well-being obtained through the economic side of the relationship by means of increased energy use could in some circumstances be completely cancelled by the associated damage to wellbeing through the environmental side. Not only has this outcome probably already occurred for some energy sources in some locations, but under continued growth it is eventually inevitable overall, irrespective of the energy sources chosen.

Conservation of energy means doing better, not doing without. Fortunately, the slowing of energy growth, and even the eventual reduction of the total level of energy use, need not mean a life of economic privation for the public. The essence of conservation is the art of extracting more well-being out of each gallon of fuel and each kilowatt hour of electricity. Much progress in this direction can be made through changes that increase efficiency in industrial processes and electricity generation, and in energy-consuming devices in homes, commerce, and transportation. Of course, some kinds of energy conservation will require changes in individual behavior, and critics of conservation are quick to suggest that this implies a return to primitive existence. In a society whose members use 5000-pound automobiles for half-mile round trips to the market to fetch six-packs of beer, consume the beer in underinsulated buildings that are overcooled in summer and overheated in winter, and then throw the aluminum cans away at an energy loss

---

[122a] A particularly cogent and eloquent formulation of the arguments for both points was recently published by Amory Lovins, "Energy Strategy: The road not taken".

[122b] These arguments were first published in slightly abbreviated form in John P. Holdren, "Too much energy, too soon", *New York Times*, Op-Ed page, July 23, 1975.

equivalent to one-third of a gallon of gasoline per six-pack, the primitive-existence argument strikes us as the most offensive kind of nonsense.

Saving a barrel of oil is generally cheaper than producing a barrel. Slowing the growth of energy consumption by means of rational conservation measures can actually save a great deal of money. For, although technological improvements to increase energy efficiency often require some additional capital investment over conventional practice, this investment is usually less than the investment that would be needed to produce from new sources (offshore oil, nuclear fission, geothermal development) an amount of energy equal to that saved. In this sense, conservation is the cheapest new energy source. The money saved by conservation, of course, would in principle be available for some of this country's many other pressing needs.

Less energy can mean more employment. The energyproducing industries comprise the most capital-intensive and least labor-intensive major sector of the U.S. economy. Accordingly, each dollar of investment capital taken out of energy production and invested in another activity, and each dollar saved by an individual by reduced energy use and spent elsewhere in the economy, is likely to benefit employment.

We conclude therefore that the high rates of growth of energy use and electricity generation traditionally anticipated for the period between 1975 and 2000 are *neither desirable nor necessary*. They are not desirable because the economic, environmental, and social costs of such growth are likely to be severe; they are not necessary because the application of a modicum of technological and economic ingenuity can produce continued -- indeed, growing -- prosperity without them.

Both in the short term and thereafter, then, the mainstay of a rational energy policy for this country should be learning to do more with less. Some efforts at more efficient use of energy will come about automatically through the impact of higher energy prices. Even without industry price-gouging, these are inevitable because of the technical intractability, in various respects, of the energy sources that remain. Price is likely not to be a sufficient incentive to wring from the socioeconomic system all the increased efficiency that is possible and desirable, however, primarily because of certain differences in perceived interests of industries and consumers; regulations such as efficiency standards for appliances, automobiles, and buildings should therefore be used to supplement the price mechanism. And "lifeline" rates and other subsidies to the poor should be instituted to alleviate the impact of higher prices on those least able to make energy-saving adjustments.

Environmentally, the first step is to clean up the mainstays of the present energy budget, the fossil fuels. Special attention must be given to finding environmentally tolerable ways to exploit the abundant resources of coal and possibly of oil shale. The environmental and social risks of fission, including the threat of terrorism and sabotage, either at the facilities or elsewhere by using stolen nuclear materials, deserve the most searching reevaluation before a national commitment is made to expand reliance on this source. In our own view, the threat posed by fission power to the fabric of the social and political system through the spread of radiological and explosive nuclear weapons -- a threat that is a virtually inevitable concomitant of this energy technology -- is *qualitatively* different from the risks of other energy technologies, and indeed a price not worth paying for the benefits of fission power. But the choice is more a social and political one than a technical one, and it should be made not by scientists but by the broader public.

The many forms of solar energy deserve vigorous investigation to find the ones most benign environmentally and most practical technically. Attention should be focused not merely on centralized electric power stations but on the myriad possibilities for dispersed applications. Fusion and geothermal power also deserve further investigation to learn whether they can meet, in a practical way and at an affordable price, the conditions of low environmental impact so essential in any long-term energy source.

It should be recognized by now that there is value in diversity in technological systems as well as in biological ones. Diversity is insurance against uncertainty, and for insurance one should be prepared to pay something. Society should not build only the cheapest energy technologies, nor even only the ones that seem on today's analysis most benign environmentally. If threats over-

looked or underrated today turn out to be important, altering a mix of energy technologies will be easier and less disruptive than abandoning a monoculture. At the same time, one should not conclude from an exaggerated preoccupation with diversity that society must develop all possibilities; the very value of diversity is to secure the flexibility to say no to those possibilities that clearly are unsuitable.

Transportation

Fuel burned for transportation in industrial nations accounts for 15 to 25 percent of all energy used by such countries. Including the energy used to manufacture and maintain the transportation systems would raise that figure to 25 to 40 percent of the total energy use (refer to Chapter 8 for details). Transportation's contribution to pollution may be taken at a first approximation to be proportional to its share of energy use; its impact on nonfuel resources is also large. Perhaps most important, transportation systems are major forces in determining the use of land and shaping the human environment. What have been the forces that have influenced this system, and how might they be changed for the better?

The automobile. The introduction of annual automobile model changes by General Motors in 1923 quickly pushed most competitors out of business, reducing the number of automobile manufacturers in the United States from eighty-eight in 1921 to ten in 1935. Only four of any economic significance remain today. A few companies therefore have been able to manipulate both demand and quality in a way that has resulted in a continual high output of overpowered, overstyled, underengineered, quickly obsolescent, and relatively fragile automobiles. These characteristics of the automobile, together with the dominance of this form of personal mobility over many more sensible alternatives, are responsible for a remarkable array of demands on resources and environmental problems. For example, immediate relief from a major portion of our air-pollution problems and a substantial reduction in the demand for steel, lead, glass, rubber, and other materials would result from the replacement of existing automobiles with small, lowhorsepower, long-lasting cars designed for recycling. And, of course, the savings in petroleum would be spectacular. If the average size of the American cars on the road in 1970 were reduced to that of European cars, the gasoline saved would have run the cars of Europe for that year!

To facilitate a shift to smaller cars, the U.S. government might remove tariffs and import restrictions on automobiles that meet strict exhaust-emission standards, so that small foreign cars would become even more attractive to American buyers. Heavy excise taxes on large Detroit products and reduced taxes on small, gas-economical ones would help shift buying habits in the domestic market. Gasoline consumption, exhaust emissions, and the components of air pollution produced by the wear of tires on asphalt and from the asbestos of brake linings would all be

reduced by the use of smaller, lighter cars. Recycling old automobiles and building longer-lasting ones would reduce both the consumption and the environmental impact of obtaining resources, as well as reducing the pollution directly associated with automobile production. The rewards of such a program would not be limited to pollution abatement and the saving of petroleum and other resources. Because small cars need less room on the highway and in parking lots, transportation would *through that change alone* become pleasanter, safer, and more efficient.

Of course, there would be several adverse consequences of even such a mild program of "automobile control." Between 10 and 20 percent of the American population derives its living directly or indirectly from the automobile: its construction, fueling, servicing, selling, and the provision of roads and other facilities for it. Not all of these jobs would be affected by conversion to smaller, more durable automobiles and to other forms of transportation, but many would be. In the long run, workers displaced from auto production could be employed in ways that would reduce reliance on environmentally destructive technological processes in other industries.

Unless there were careful planning to ameliorate the consequences, such a conversion could have extremely disruptive effects on the national economy. The economy, however, is demonstrably capable of accommodat-

ing itself to very far-reaching changes. Even without extensive planning, for example, the United States economy converted almost 50 percent of its productive capacity from war-related products to peacetime products between 1946 and 1948. The flexibility of our economic institutions is often grossly underestimated.

Public transportation. One of the great difficulties with conversion from automobiles to public transportation has been the tendency to seek flashy, expensive, "space-age" solutions to America's transport problems. [123] In case after case, aerospace companies and contractors have promoted such technological circuses, and in several instances they have succeeded in having them produced. The crowning blunder may be BART, San Francisco's Bay Area Rapid Transit system. That system is a double tragedy -- not only has it not accomplished what it set out to do, but it has tended to give new ventures in mass transit an undeservedly bad reputation (Box 14-5). BART cost a fortune to build and has proven inordinately expensive to run. Since its delayed opening, it has been constantly plagued with malfunctions. Perhaps most discouraging, despite carrying full loads in rush hours, BART has not appreciably diminished automobile traffic in the Bay Area.

It is clear that much more sensible urban planning must be done if cheap, reliable, and efficient mass transport is to replace a significant portion of the automobile traffic in cities and suburbs -- as it seemingly must if Americans are to retain much of their mobility into the twenty-first century. [124] It may well be that what *Consumer Reports* called the "moonshoot mentality" has moved planners too far toward a pattern of expensive new rail systems "that offer riders sleek

cars with 'space-age' features." The way of the future -- at least for urban areas -- may be more in the direction of buses, perhaps in some cases powered by flywheel systems. [125]

In the meantime, paratransit -- a mix of partial solutions including special bus lanes on freeways, wellorganized car-pooling, reform of taxi regulations, and expansion of bus service -- might be a big help. [126] Many such schemes were introduced in early 1974, stimulated by the energy crisis. But when gasoline was again plentiful, if no longer so cheap, many of the car-pooling arrangements were abandoned and bus and train use again declined. Little-used "diamond" lanes reserved for buses and car-pools on California freeways, rather than encouraging car-pooling, became a source of considerable resentment by commuters crowded into the remaining lanes. Eventually, they were abolished. Apparently, one of the greatest obstacles to establishing a sensible transport system is the addiction of the American public to fast personal cars.

Railroads. Whatever the ultimate solutions to urban transport problems in the United States may be, it is evident that they should be integrated with a restored and revitalized national rail network. Federal funds should not be committed, for instance, to any rail projects that are not standard gauge (and thus cannot be integrated into the existing network). It goes without saying that an enormous effort will be required to reestablish decent passenger train service accessible to most people. The Amtrak program has fallen far short of this goal. [127] This is tragic, since railroads not only are by far the most energy-efficient transporters of people, they are much less disruptive of the landscape than superhighways, and their terminals do not gobble land as jetports do. [128]

Much more money, including all gasoline taxes not needed for highway maintenance should be allocated to rebuilding the railroads. Moreover, planners must redesign the system so that, unlike the present Amtrak (and, of course, the Interstate Highway system), it does not promote the growth of cities at the expense of rural areas. Amtrak routes are designed much like airline routes, focusing on schedules between relatively large and distant cities. Intermediate areas have no service, or have service at extremely inconvenient hours. BART-type

---

[123] Actually, the United States at one time had quite good urban electrified rail transit systems. They were dismantled following shortsighted decisions promoted by, among others, General Motors. See John E. Ullman, Getting the rails back.

[124] As long as fuel remains relatively cheap and automobile use relatively unrestricted, it looks as if *no* system of mass transit would make much of a dent in energy use or traffic congestion. See Robert Lindsey, *Mass transit, little mass*.

BOX 14-5 Bay Area Rapid Transit: A Case History

In 1957, when the California legislature created the Bay Area Rapid Transit District (BART), electric trains of the existing Key System joined San Francisco with cities on the other side of San Francisco Bay. The Key System used part of the lower deck of the Oakland Bay Bridge, and consisted of five lines with 55.9 miles of track. * Because of declining patronage in the 1950s, the system was said to be losing $350,000 annually and in need of $4.5 million to renovate its tracks. In 1958 the Key System was closed down.

In 1962 voters in three Bay Area counties, after a propaganda campaign financed in large part by contractors and others hoping to profit from the building of BART, voted a $792million bond issue for its construction. The system was to provide fast, convenient commuting to San Francisco, and relieve the glut of automobiles that was choking the city and befouling the air in an area once renowned for its beauty. A first blow was dealt to those aims when counties both north and south of the city voted not to join the system, which was then constructed with 25 of its 34 stations in the East Bay (east across the bay), where only 17 percent of the commuters who worked in San Francisco lived (60 percent of those who work in downtown San Francisco live in the city itself).

In late 1974 BART was finally in "full" service -- well behind schedule and at a cost of $1.6 billion rather than the programed $1 billion. It thus cost 350 times as much to build as it would have cost to repair the Key System (230 times, if corrected for inflation). In 1975 it was losing about $20 million per year, or 60 times as much as the Key System. But even at that cost, service was far from satisfactory. The space-age design featured, among other things, streamlined cars and fully computerized controls for what was described by promoters as a "modern 'supported duorail' system" (English translation: train on train track).

In a surpassing bit of folly, the "supported duorails" were not made standard gauge, so standard railroad cars cannot be run on them, and the system cannot be hooked into existing rail lines. The flashy looking BART trains have cars slanted at one end at front and rear. Consequently, cars can only be removed from or added to the center of the train, vastly complicating the process of changing the length of cating between rush and nonrush hours. The cars, purchased from an aerospace company, have been plagued with troubles, exacerbated by the total absence of test track in the original system plan.

The ultimate fiasco, however, was the fail-safe automatic train-control system designed by Westinghouse (which also builds "fail-safe" nuclear power reactors) so that human operators would be unnecessary. Trains roared past stations; doors opened between stations and refused to open at stations; phantom trains were "detected" and real trains were lost by computers, each time causing the whole system to grind to a halt; trains ran at erratic speeds. Chaos ruled. For months a train was not allowed to leave a station until notified by a BART employee over the telephone from the next station that it was safe to proceed. Eventually a traditionally designed signal system had to be installed at additional cost.

Whether the automated system will ever function properly and reliably is questionable. What is clear is that BART has made no significant difference in the automotive congestion in San Francisco. The majority of its riders have switched to BART from commuter bus lines and car pools, and a substantial number seem to be shoppers who used to shop in the East Bay.

After two years of operation, some of the most annoying malfunctions of BART had been conquered, and a rapid ride in the clean, comfortable cars provided a striking contrast to the average subway or commuter train. Nevertheless, BART appeared to be the wrong system in the wrong place -- hugely expensive and not designed to serve the real transit needs of the area. It was intended as a service for commuters from wealthy bedroom communities, not for people of the city (especially the poor). It thus subsidized both urban sprawl and the rich. Whether, in an era of increasingly expensive gasoline and, it is hoped, of increasing restrictions on automotive commuting, BART will even fulfill that mission remains to be seen.

---

*Information on the Key and BART systems is taken from Trouble in mass transit: Why can't the people who put a man on the moon get you downtown? *Consumer Reports*.

systems may make it simpler for the wealthy to live outside decaying cities; Amtrak makes it less desirable to live and work in small towns and rural areas. Such patchwork solutions will not work; the planning of our national transportation system must be comprehensive because of the massive social impact of that system.

Stimuli for change. Despite the obviously growing need for an overhaul of the transport system in the United States, it seems unlikely it will be changed significantly for the better until the public becomes sufficiently fed up with smog, noise, delays, and danger that it is willing to forego further growth in both the automobile population and the gross national product. Emissions from automobiles have been lowered and certainly will be reduced even further, but until the public rebels against cars, their numbers will probably increase rapidly enough to keep the overall smog level dangerously high and gas consumption rising, as more and more land disappears under freeways. The problem is worst in the United States, but a similar trend exists in other DCs.

Growing energy problems may eventually provide the needed catalyst for a rebellion against cars. One cheering sign by the mid-1970s was a dramatic increase in bicyling, leading even to the designation of bike lanes in the streets of some municipalities. Whatever can be done to stimulate a bicycle cult to rival the big-car cult should be done. If and when a transition can be made to a nongrowing population and economy, both the need for business travel and the pressure to build more vehicles and more goods should be reduced; perhaps then a rational and comprehensive land, air, and water transport [129] system for the nation can be developed.

The kinds of transport problems that now plague the DCs (the United States in particular) can (and we hope will) be totally avoided in most LDCs, where there is still an opportunity to build systems based primarily on a mix of low-cost mass transit and bicycles. [130]

Communications

Unlike most other institutions, the communications system may have great potential for instituting positive change in individual attitudes and the direction of society. [131] Television and radio seem to have universal appeal and with relatively little expenditure could have virtually universal coverage. If human problems are to be solved on a worldwide basis, some means of intercommunication among the peoples of the world must be employed. One possibility is for the DCs to supply LDCs with large numbers of small, transistorized TV sets for communal viewing in villages. Such sets could provide the information channels for reaching the largely rural populations of the less developed world. These channels could provide both a route for supplying technical aid and a means of reinforcing the idea that the people are members of a global community. Such a project is already underway in Indonesia, [132] and a satellitebeamed program was used experimentally with great success in India until the satellite service was terminated in 1977. [132a]

Isaac Asimov has described the potentialities of electronic communications as a "fourth revolution" on a par with the developments of speech, writing, and printing. [133] Considering the enormous influence of radio and television in Western countries, their future impact in largely illiterate societies can hardly fail to be even greater. But that revolution will not realize its full potential until electronic communications are as widespread and commonplace as the printed word now is, and until ways are found to provide feedback from the viewing public into the communications network.

Communications satellites. The first small commercial communications satellite station was launched in 1965, with one channel for television and 240 relays for voice transmissions. A much more sophisticated system, INTELSAT IV, was initiated in 1971 with the launch-

[129] In some areas, canals and other inland waterways can be very efficient in moving freight. See M. G. Miller, *The case for water transport*.

[130] See Ivan Illich, "Energy and equity"; and Alan K. Meier, "Becaks, bemos, lambros, and productive pandemonium", *Technology Review*, Jan 1977, pp. 56-63.

[131] *Scientific American*, September 1973, was a special issue on communications that included several articles pertinent to this discussion.

[132] Cynthia Parsons, Indonesia studies best use of TV, Honolulu *Advertiser*, March 11, 1975.

[132a] India, however, planned to continue much of the rural program using ground stations (Yash Pal, A visitor to the village, *Bulletin of the Atomic Scientists*, January 1977, pp. 55-56).

[133] The fourth revolution.

ing of two satellites. By 1975 the INTELSAT IV system was complete with seven satellites in place, three over the Atlantic Ocean and two each over the Pacific and Indian oceans. Eighty-six member nations were being served by 80 Earth stations with 103 antennas in 58 countries. [134]

The system has permitted a number of countries that previously had had virtually no contact to communicate with each other by satellite. An interesting example is Chile and Argentina; the

Andes were once too great a barrier. INTELSAT transmits data, transoceanic telephone and teletype messages, television broadcasts, and facsimilies of letters, newspapers, or photographs. Distributional satellites are also being established to relay messages within countries as a supplement to the international INTELSATs. Eventually, the hope is to develop a system for broadcasting directly to each home. This is not expected to become a reality before the 1980s, however, and even then many think it will be limited to the sort of service described above -- programs beamed to schools, community centers, and villages, especially in LDCs.

The potential for creating a true "global village" through such a communications network should not be ignored. Even apart from the opportunity to bring diverse peoples together for exchange of ideas and information, there is a great opportunity for a general lowering of hostilities. Familiarity breeds friendship far more often than contempt.

Programming and propaganda. There remains, of course, the substantial danger that a worldwide communications network will not be used for the benefit of humanity or will further erode cultural diversity. If, like the television system in the United States, it is employed to promote the ideas and interests of a controlling minority, the world would be better off without it. [135] If it is used to create a global desire for plastic junk and the Los Angelization of Earth, it would be a catastrophe. Concerns over this and related programming problems have already been raised at the United Nations. One delegate, for instance, correctly pointed out that "Films considered the acme of art in one country [might be] judged pornographic in another." [136] The problems of supplying channels for information are thus easily solved in comparison with the problems of determining what information should flow along those channels and in what format.

Much programming ought to be informational, even if presented as entertainment. People in the LDCs need help in increasing agricultural production and improving public health, as well as information on the need for population control and the ways it may be achieved. Programming should be carefully designed by social scientists and communications experts thoroughly familiar with the needs and attitudes of the audiences in each country or locality. This is particularly important in the LDCs, where it will be especially difficult because of the lack of trained people and the radical change in attitudes that is required. Control of the communications media obviously should be public, with maximum safeguard against abuses and against the problems of "cultural homogenization." The problem of controlling "Big Brother" will be ever present in all societies.

Educating people in the developed nations to the problems of population and environment is not too difficult, assuming time and space can be obtained in the media. Material can be more straightforward, since in most DCs there is already rather widespread awareness of many environmental problems. In the United States a great step could be taken merely by requiring that both radio and television assign some of their commercial time to short public-service "spots" calling attention to the problems of population, resources, and environment. This could be justified under the equal-time doctrine that put the antismoking message sponsored by the American Heart Association and the American Cancer Society on TV (see "Advertising" section). The FCC might be empowered to require that networks donate time for ads to awaken people to the population-resource-environment crisis. Such spots, sponsored by voluntary

organizations like Planned Parenthood, ZPG, and the Sierra Club, have been moderately effective in drawing public

[134]Information on INTELSAT is from Hughes Aircraft Company, *Intelsat IV case history*: vol. 2, The international satellite communications system: Intelsat IV, Hughes Aircraft Company, El Segundo, Calif., December 1974. A more recent source is Burton I. Edelson, Global satellite communications. *Scientific American*, February 1977, pp. 58-73.

attention to the problems. Unfortunately, the advertising budgets available to these groups are puny compared to those of General Motors or Exxon. Long documentary specials, whether prepared by the networks or by educational stations, seem relatively ineffective in initiating awareness of a problem, although they are useful in providing detailed information. For the most part, they reach only those who are already aware that a particular problem exists. Most people want to be entertained; they do not want to hear bad news.

Moving information instead of people. In the longer term, more ambitious exploitation of the potential of communications systems may help to relieve pressure on energy supplies and other resources. Specifically, it is far less costly in terms of energy to move information than to move people and things. Computer terminals coupled to television sets (for graphic display and face-to-face conversations) and to telephone lines (for data transmission) could eliminate the need for commuting to and from work in many kinds of jobs. Newspapers, which today are responsible for the consumption of great quantities of wood pulp, could be displayed a page at a time, under the control of the reader, on the computertelevision hookup. Scientific and business meetings, each of which now entails hundreds of thousands of passenger miles of fuel-gobbling jet travel, could be managed on closed-circuit television for a tiny fraction of the impact on resources.

Of course, there are problems to be surmounted before such schemes can be implemented, not the least of which is the protection of privacy and confidential communications. Such difficulties can, in principle, be solved, and it seems clear that the communication -- informationprocessing area is one field in which technological innovation can make important contributions to alleviating the resource-environment crunch.

Land Use

Land use has become a catch phrase in the contemporary environmental debate, but the term calls forth very different images and priorities in the minds of different groups of people. This is so because so many of the compelling social and environmental issues of the day are tied rather directly to how the land is used. Urban decay, the existence of ghettos, lack of access to decent low-cost housing, and the problem of busing of schoolchildren can all be viewed as interrelated consequences of prevailing patterns of urban land use. Another aspect of the pattern is suburbanization and the energy-intensive long commutes to work that go with it. The loss of prime agricultural land and recreational open space under settlements, industrial parks,

transportation systems, and energy facilities is yet another dimension. And certainly the conflict of development of land versus continued provision of essential services by natural and lightly exploited ecosystems (perhaps most strikingly apparent today in the destruction of estuaries and wetlands) is a central ingredient of the human predicament in the long term.

Increasingly, the opinions of thoughtful policymakers and observers are converging on the view that the resolution of the problems just enumerated will require a degree of comprehensiveness in land-use planning that exceeds anything contemplated previously in the United States. (Some other Western countries -- the United Kingdom and Sweden, for example -- have been flirting with comprehensive planning for longer. [137]) Here *comprehensive* means integrating systematically society's social and environmental goals with the pattern of land use on regional and national scales. It is clear, of course, that such comprehensive planning, even if successful, is not a *sufficient* condition for the solution of social and environmental problems, but a strong case can be made that it is a *necessary* one. In the remainder of this section of text, we first discuss some goals of land-use planning and policy and, second, the tools for pursuing those goals and the obstacles that make the task a difficult one.

Goals. The planner's easiest task is setting down desirable goals (easy, at least as long as one does not inquire too closely about making them all compatible with each other). Here is our own partial list.

---

[137] Peter Heimburger, *Land policy in Sweden, Ministry of Housing and Physical Planning*, Stockholm, 1976. On this and many other points raised here, see also the excellent book by William H. Whyte, *The last landscape*, Doubleday, Garden City, N.Y., 1970.

1. Central cities should be restored to attractiveness and economic viability. In respect to location, absence of competing uses, value of existing structures, and potential for cultural and racial integration, they are much too valuable to waste.
2. Housing developments should be planned in ways that integrate low-cost and higher-cost units and that provide for community open space and resourceconserving community recreational facilities (instead of private) -- swimming pools, workshops, darkrooms, and so on.
3. Settlement patterns and transportation systems should be integrated in ways that minimize commuting distances and reliance on the private automobile.
4. Construction of settlements should avoid areas especially prone to flood, fire, landslide, and earthquake.
5. Prime agricultural land should be defended absolutely against encroachment by all other potential uses. The world food situation and the high environmental impact of bringing marginal land under cultivation dictate this highest priority for good land already under agricultural use.
6. Land areas that have remained in wilderness or near-wilderness condition until now should be preserved as such, permitting them to serve aesthetic and ecological functions inconsistent with exploitation or development. More intelligent and efficient use of land already being exploited is preferable to further encroachments on wilderness.
7. Nonwilderness areas where ecological processes perform particularly crucial services in

support of civilization should be identified, the extent and value of their services clarified, and the land withdrawn from uses of lesser value that are incompatible with the continued provision of the natural services. Filling of wetlands and estuaries for residential development is an example where even on present knowledge a complete prohibition clearly is justified.

Tools and obstacles. On the assumption that the foregoing or some other set of goals were agreed upon by policy-makers, the question would remain what tools are available with which the goals might effectively be pursued. Among those that have been used or contemplated for land-use management in the United States are: zoning ordinances; preferential tax assessment of different types of land; government purchases of open space; selective siting of facilities owned or substantially supported by government; control of building permits to establish local growth ceilings, moratoria, or timed development contingent on meeting specified conditions; use of the environmental impact statement to force consideration of adverse impacts and alternatives; and government-funded urban renewal projects. [138]

The use of zoning as a tool for land-use planning and management has suffered from three difficulties. The first is fragmentation among the decision-making entities, rendering comprehensive planning or results impossible. In California alone, more than 1400 government entities are involved in zoning. [139] Special-purpose agencies dealing with housing, air pollution, water pollution, energy development, and fish and game (to continue with the California example) separately pursue interests that should influence zoning decisions, but there is no general mechanism for exerting such influence and no effective machinery for coordinating the goals of the agencies. The result of this partial vacuum is fragmented control of zoning by local communities, most of which do so in pursuit of a perceived interest in local growth. [140]

A second difficulty with the zoning tool is the questionable constitutionality of zoning ordinances that are discriminatory in practice, even if not in intent. Keeping density down by zoning the land remaining in a community for single-family dwellings on two-acre lots may succeed in preserving a status quo that the current inhabitants cherish, but it excludes low-income people and thus preserves a residential stratification that is undesirable for society as a whole. The likelihood that zoning ordinances having this effect will eventually be found unconstitutional places in jeopardy other, more

---

[138] A more extensive discussion of these tools than space permits here can be found in CEQ, *Environmental quality--1974*. See also Elaine Moss, ed., *Land use controls in the United States*.

[139] On this and other aspects of land-use planning in California, see the very useful study by the Planning and Conservation Foundation, *The California land: Planning for people*, Kaufmann, Los Altos, Calif., 1975.

[140] The dynamics of this process and the fallacies underlying the belief that such growth necessarily will be beneficial are examined perceptively by Harvey L. Molotch, The urban growth machine, in *Environment*, William Murdoch, ed., Sinauer, Sunderland, Mass., 1975.

enlightened uses of the zoning tool, as well perhaps as other land-use controls. [141]

A third difficulty with zoning that also carries over into the other forms of control is the question of what forms of regulation really are legally a "taking," requiring compensation of the landowner. Involved here is the basic conflict between the rights of a holder of private property -- one of the most cherished American traditions -- and the public's interest in sound and coordinated management of land. [142]

Close to zoning in influence on land use is taxation, although the influence of taxes on use may be inadvertent more often than it is used as a tool. Certainly one of the major driving forces behind the development of prime agricultural land in the United States has been the almost universal practice of assessing land for taxation on the basis of the land's most valuable potential use. Unfortunately, agricultural land has lower market value than developed land. Thus the spread of suburbs has led to assessment of adjacent agricultural land at the value it would have if subdivided for residential or commercial development. This leads of course to taxes that the agricultural revenues from the land cannot support and forces the farmer to sell out. In this way, assessment of the land as a potential subdivision leads inevitably to realization of the potential. Some states have begun to experiment with legislation permitting agricultural lands to escape such discriminatory and crippling taxation. *California's Williamson Act*, one of the more widely publicized examples, has proven too narrow and restrictive to be of great value, however, and more comprehensive measures are needed. [143]

The imposition of ceilings or moratoria on local growth by a few communities around the United States -- Petaluma and Pleasanton, California, and Mount Laurel, New Jersey, for example -- has attracted much attention. These decisions have been implemented through control of building permits, made contingent in some cases upon achieving in the community some specified level of adequacy of sewage systems, schools, water supply, or other factors. Like zoning practices, this approach has come under sharp legal scrutiny to determine its constitutionality. [144]

Possibly as important as all the tools that have been used by policy-makers to influence patterns of land use intentionally have been the inadvertent effects of government investments in certain kinds of growth-shaping facilities. Transportation systems -- most notably the interstate highway system, but also airports, ports, and mass-transit systems -- have been especially influential. So have water projects, sewage lines, and watertreatment plants, and centers of government research and bureaucracies. [145] Unless these influences are thoroughly understood and taken into account deliberately and comprehensively, other approaches to land-use planning have little chance to succeed.

All of the foregoing difficulties underline the necessity for a more coordinated approach to land use in the United States than any that has been implemented up until now. Balancing priorities among competing uses is at the core of the problem, and this can only be done in a sensible way on a regional (collections of counties or a state or states) or national level. An example of what might be accomplished if the political obstacles were overcome is offered by the remarkable *California tomorrow plan*, already discussed. [146] The plan describes how trends now underway in California would lead, if unchecked, to significant disruptions in the well-being of the people

of the state before the year 2000, and it describes a more sensible alternative future based upon a state zoning plan. The goals of the land-use plan are very similar to those listed above.

Perhaps the most comprehensive approach to planning that has a reasonable chance of being enacted in the near future is the California Coastal Plan, produced on the mandate of a statewide ballot initiative in 1972 and delivered to the legislature in December 1975. The plan covers the 1600-kilometer California coastline in a strip extending inland to the coastal mountains, an average

[141] Some recent court decisions are described in CEQ, *Environmental Quality*, 1975, pp. 186-187.
[142] An extended discussion of this point is found in Planning and Conservation Foundation, *The California land*.
[143] Planning and Conservation Foundation, *The California land*, p. 49. For a more general discussion, see CEQ, *The impact of differential assessment of farm and open land*, Government Printing Office, Washington, D.C., 1976.
[144] See, for example, CEQ, *Environmental quality*, 1975, and Molotch, The urban growth machine.
[145] CEQ, *The growth shapers: Land-use impacts of infrastructure investments*, Government Printing Office. Washington, D.C., 1976.
[146] Alfred Heller, ed., *The California tomorrow plan*.

width of perhaps 8 kilometers. It takes account of the competing pressures of energy development, residential use, transportation, recreation, and ecological values, and offers guidelines and machinery for resolving the conflicts in a systematic way.

As with all ambitious undertakings, it is no doubt possible to find flaws in the *California tomorrow plan* and in the much more detailed California Coastal Plan. The question, however, is not whether they are flawed but whether they represent a substantial improvement over the status quo. We believe that they do, and indeed that they are illustrative of the sort of thoughtful and systematic approach that must find application around the country if planning for the rational use of land is to emerge from the disarray that has characterized land use in the United States until now.

A QUESTION OF GOALS

It is fitting to close this chapter with some reflections on the long-range goals of Western society. Can they be, as English economist Wilfred Beckerman apparently thinks, economic growth for the next 2500 years? [147] Beckerman reasons that since growth has occurred since "the days of Pericles," there is "no reason to suppose that it cannot continue for another 2500 years." It turns out that he is wrong on both counts. Careful studies of economic conditions in England for the past 600 years or so, for example, show average growth rates on the order of 0.5 percent per year--one-tenth of the 5 percent envisioned by most growthmen for "healthy" economies.

Social scientist Jack Parsons has done some interesting extrapolations that put long-continued economic growth in perspective. He extrapolated economic growth in England*backward* at the conservative rate of I percent per year. At the time of Pericles (490-424 B.C.), at that rate the annual income of the average household would have been 1.5 ten-millionths of a penny. Hence, even Beckerman's history is bad -- growth cannot have gone on since the time of Pericles at even the "low" rate of 1 percent per annum. Careful historical analysis indicates that fluctuation rather than constant growth has been the fundamental characteristic of Western culture's economic history. The purchasing power of builders' wages in southern England reached a peak between 1450 and 1500 that was not attained again until the late years of the nineteenth century. [148]

Economic boom clearly is not and cannot be a long-term phenomenon. Until about 1950, economic growth rates of more than 2 percent per annum were very unusual. The 4, 5, or even 6 percent growth rates that economists now seem to regard as the norm are in fact a phenomenon in which a few countries are exploiting much more than could conceivably be considered their fair share of the planet's resources over a time span of a quarter of a century. Assuming conservatively that human beings have had a 1-million-year tenure on Earth, it is clear that human societies have existed in what Beckerman would undoubtedly consider economic stagnation for 99.99 percent of that tenure.

Economic growth -- that is, per-capita increases in the availability of goods and services -- throughout recorded history has been engendered by two sets of circumstances and/or a combination of them. The first such set is the development of widescale economic integration, which allows for the development of more efficient organization of resources, human and natural. The Hellenistic world, from Alexander the Great until the birth of Christ, was an example of such a set. [149] So were the uniting of former British colonies into the United States and, later, the European Economic Community.

The second and more common set of circumstances has been one in which some group on the periphery of a central cultural zone has managed to gain control over the exploitation of some vast hinterland and then serve as the broker between that resource-rich frontier and the high-consuming metropolis. For example, the rich and attractive Minoan culture on the island of Crete controlled the trade from Egypt and western Asia to the Greek lands to the north in the middle of the second millennium B.C. The Hanseatic League of the high Middle Ages had outposts from London to Novgorod

---

[147] Beckerman's views are cited by Jack Parsons in The economic transition, from which most of our figures on growth, past and future, are taken.

[148] Phelps Brown and J. Hopkins, Seven centuries of the prices of consumables, compared with builders' wage rates, *Economica, NS vol. 23 (1956), November, pp. 296-314.*

[149] See Mikhail Rostovtzeff, *Social and economic history of the Hellenistic world*.

that plucked herring, furs, lumber, and all manner of resources from the North Sea and Baltic basins and sold them to medieval Europeans, while ornamenting the cities of Hamburg, Bremen, and Lübeck with an elegance and prestige still visible. The Dutch monopoly on the spice trade in

the seventeenth century supported the artistic flowering that is best known to us in the work of Rembrandt van Rijn. Finally, the race for empire of recent centuries, characterized above all by British majesty and wealth before 1945, sponsored the most recent expansion, which allowed the citizens of the DCs to enjoy a now-declining affluence. [150]

Systems of economic integration are always very fragile, and the pattern of economic growth based on the hegemony of exploiters over the resource-rich frontier seems to carry the seeds of its own destruction. In order to exploit an area, it is necessary to organize it, either by organizing the indigenous population or by sending forth emigrants from the metropolis. What starts out as an organization for economic exploitation consistently tends to become an organization for political resistance to the metropolis and finally a cadre for political and economic independence. The Ariadne legend in Greek literature, retold in a sagacious reconstruction of its historical context by Mary Renault in *The King Must Die*, tells a story of the Greeks breaking the economic hold of the Minoans on their culture. The *Iliad* was probably the story of a postdecolonization war fought over control of the pottery trade, rather than over the beautiful Helen. The disintegration of the British Empire and the other European overseas empires of the recent past began even before the empires were fully formed.

The loss of mastery over an erstwhile dependency does not necessarily mean that the resources of that area are lost to the metropolis as a whole. But it usually does mean comparatively hard times for the previous proprietors of the resources and a better deal for the new owners. Minoan culture was completely obscured until its rediscovery in the early years of this century. The development of Baltic powers reduced Hamburg, Bremen, and Lübeck to places of only local significance as Europe moved into the modern period. Casual perusal of current daily newspapers will illustrate the cost to Britain of inflexibility in the face of change.

Economic growth since the days of Pericles has been spastic and dependent rather than inexorable and selfgenerating as Beckerman would have it. When a society has achieved a transient economic integration or gained control over some neglected bonanza, its economy has grown. The bonanzas of our planet have pretty well been found by now, and those remaining are slipping ever more surely into the hands of proprietors resident in the lands where they occur -- the OPEC nations, for example. Americans and Europeans will have to settle down to a lifestyle set against the background of a declining resource base. While today's technological sophistication may put us in a better position to ameliorate the effects of the end of the boom than were, say, the Minoans, it also gives us the means to destroy civilization in the process of squabbling over the tail end of the resources. Furthermore, those past booms did not end with the entire planet overpopulated and severe ecological constraints limiting what new technologies could be adopted -- something invariably ignored by economic Pollyannas whose "historical perspective" rarely extends beyond the beginnings of the most recent boom. [151]

What are the prospects for the future? Setting aside the physical and biological constraints that were already beginning to limit growth by the mid-1070s, could sustained growth reasonably be expected for the next 2500 years? A simple calculation by Parsons shows Beckerman's view of the future to be as preposterous as his view of the past is fallacious. Again Parsons uses a modest 1 percent per annum growth rate. This gives a doubling time of 70 years -- a lifespan -- so that on the average each person is about twice as well off at death as at birth. At this rate a person's

wages for an hour of work reach 1 million pounds (about $2 million) an hour in a little more than 1500 years, and at the end of Beckerman's 2500 years of growth, "a small child's pocket money, at say, 0.5 percent of the GNP per capita per week (one shilling and sixpence a week in 1970) would be five thousand million pounds."

---

[150] For a masterful account of the impact of the West's most recent resource capture, see Walter Prescott Webb, *The great frontier*. The historical discussion in this section owes much to historian D. L. Bilderback.

[151] For example, see Glenn Hueckel, A historical approach to future economic growth. Heuckel's "historical" perspective extends about 200 years, not even to the beginning of the Western boom. Needless to say, the article shows a characteristically blissful ignorance of ecology.

To emphasize the absurdity of there being 2500 more years of economic growth in England, Parsons describes what he calls the "millionaire barrier." At the I percent growth rate, the average person would have the living standard of a millionaire (income of £100,000 per year) just before 2400 A.D. At a "normal" growth rate of 5 percent per year, the millionaire barrier would be reached in 85 years. Parsons then asks the logical question: once everyone is a millionaire, who will generate the goods and services that everybody wants to consume?

Our long-range goal, then, cannot be continued economic growth. Indeed, the main justifications for growth given by economists -- that it will generate the economic power needed to "clean up the environment" and improve the lot of the poor -- imply that the consequences of growth in the future will be precisely the opposite of what they have been in the past.

We have already described the devastating effects of economic growth on the environment and the continuing efforts of growthmanic politicians and industrialists to destroy it with ever more energy use and ever more "development." The case for improving the lot of the poor through growth is equally preposterous. Although there has been considerable material improvement in the lot of the poor in industrial nations during the last century, the gap between poor and rich has not closed appreciably; indeed, in most countries (including the United States) it has widened over the past two decades. [152] And, since poverty is a relative concept and there has been a revolution of rising expectations, "in the minds of persons with low incomes . . . a $4000 income for a family of four might be less tolerable in today's society than the pittance received by the poor in sixteenth-century England." [153]

Furthermore, the gap between rich and poor nations has grown during the recent period of rapid economic growth in the DCs. This gap is even greater than that indicated by national per-capita GNP statistics because the gap between the rich and the poor within LDCs has been growing very rapidly in many of those nations showing the most "development." Thus between 1950 and 1970 the ratio between the average income of the richest 20 percent of the Brazilian population and that of the poorest 20 percent increased from 15/1 to 25/1. [154] Similar increases in inequity of income distribution have occurred alongside economic growth in Mexico, Pakistan, the Philippines, and Ghana, to name a few.

What, then, if not growth, should the long-range goals of society be? Haven't the economists explained that the opposite of growth is stagnation? The answer, of course, is that in noncancerous biological systems the opposite of growth is maturity. What a mature society should be like ought to be (but is not) a matter of wide discussion, and we are willing to make some suggestions. It will have a "dynamic equilibrium economy" [155] in which pressures on nonrenewable resources will be very nearly nonexistent, and, of course, the population will be essentially stationary. Some mechanism will have been found to escape from bigness -- perhaps through decentralization of government and industry or political fragmentation or reduction in population size or some combination of these.

There seems to be a growing consensus that bigness is basic to our problems -- that Americans may have gone to the point of social diseconomies of scale as well as material ones. [156] According to some observers, hunting and gathering societies could be counted as truly affluent because individuals could fully supply their simple needs with a few hours of work each day. [157] But, perhaps more important, groups were small enough that each member of a hunting-and-gathering society was a repository for virtually all the nongenetic information -- the culture -- of that society. Each person knew who he or she was and where he or she fit in society. Alienation was not a problem. Work was not an onerous diversion from pleasure, but a fulfilling part of life itself.

In our conception of a mature society, there would be a considerably more equitable distribution of wealth and income than is found in most contemporary societies. Possibly this would be achieved by some formal mechanism. [158] On the other hand, perhaps it could be achieved

automatically as the society shifted away from the pursuit of bigness and the maximization of various indices developed by economists suffering from "physics envy," and moved toward maximizing things not amenable to statistical treatment, such as individual satisfaction and the quality of life. In a mature society the economic problem would in essence be solved.

Can a transition to a mature society be achieved in the United States? The question is obviously open. But we reiterate that a central question is that of scale. Can society escape the modern massiveness that threatens both the human environment and the human psyche today? It is probably no coincidence that the most intellectually stimulating book written by an economist in the 1970s was entitled *Small is beautiful*. [159]

States, "Sir John Kendrew has called for an international commission to monitor potential dangers behind contemporary research trends in biology. For some of this work to be carried out beneath a cloak of military or commercial security, he believes, would be dangerous. Precisely that situation is now developing. And despite the plethora of committees, we still have no assurance that any commission or other authoritative international body is doing or can do, anything about it. Sooner or later, legislation may be the only answer."
Dolan, Edwin G. 1969. *TANSTAAFL: The economic strategy for environment crisis*. Holt, Rinehart and Winston, New York. Brief and highly recommended.
Domhoff, G. W. 1967. *Who rules America?* Prentice-Hall, Englewood Cliffs, N.J. An analysis of power in the tradition of C. Wright Mills. Important reading although somewhat dated.
Dubos, Rent. 1971. *The mirage of health*. Harper and Row, New York. A critique of the health system.
Dyson, F. J. 1975. The hidden cost of saying "no"! *Bulletin of the Atomic Scientists*, June. High praise for technological circuses. (See Paul R. Ehrlich , The benefits of saying "yes.)
Easterlin, Richard A. 1974. "Does economic growth improve the human lot? Some critical evidence". In P. A. David and M. W. Reder, eds. "Nations and households in economic growth". Academic Press, New York, pp. 89-125. Reaches the depressing conclusion that "the growth process itself engenders ever-growing wants that lead it ever onward."
Egler, Frank E. 1970. *The way of science: A philosophy of ecology for the layman*. Hafner, New York. An ecologist's attempt to create a philosophy of ecology.
Ehrlich, Paul R. 1975. The benefits of saying "yes"! *Bulletin of the Atomic Scientists*, September. A reply to F. J. Dyson, The hidden cost of saying "no.
----- and R. L. Harriman. 1971. *How to be a survivor. A plan to save Spaceship Earth*. Ballantine, New York. Covers many of the problems discussed in this chapter. Contains the text of the Tugwell Constitution.
----- and J. P. Holdren. 1969. "Population and panaceas: A technological perspective". *BioScience*, vol. 19, pp. 1065-1071. Discusses the limits of technological fixes to food supply problems and concludes that many such solutions would lead to catastrophe.
-----. 1972. "The hysteria against the case". *London Times*, June 26. Reprinted in *Equilibrium* (ZPG), October 1972, and *Current Affairs Bulletin*, vol. 49, no. 10 (March

1973). A review of Maddox, *The doomsday syndrome*.
Epstein, Edward. 1973. *News from nowhere*. Random House, New York. How what is news is determined.
Esposito, J. C. 1970. *Vanishing air*. Grossman, New York. Report of the Nader task force on air pollution.
Fagley, Richard M. 1960. *The population explosion and Christian responsibility*. Oxford University Press, New York. A Protestant perspective on the population explosion and a good source of information on religious attitudes toward population control.
Fischer, D. W. 1974. "Environmental impact assessment as an instrument of public policy for controlling economic growth". *International Journal of Environmental Studies*, vol. 6, pp. 233-242.
Fisher, A. C., and F. M. Peterson. 1976. "The environment in economics: A survey". *Journal of Economic Literature*, vol. 14, pp. 1-33 (March). Comprehensive review of the ways economists have dealt with environmental problems.
Frank, Jerome. 1966. "Galloping technology, a new social disease". *Journal of Social Issues*, no. 4. Source of the descriptive phrase for one of the most serious problems we face.
Freeman, David; Pamela Baldwin; Monte Canfield, Jr.; Steven Carhart; John Davidson; Joy Dunkerley; Charles Eddy; Katherine Gillman; Arjun Makhijani; Kenneth Saulter; David Sheridan; and Robert Williams . 1974. *A time to choose: The report of the Energy Policy Project of the Ford Foundation*. Ballinger, Cambridge, Mass. A thoughtful, data-rich examination of alternative pathways for United States energy policy. Its powerful case for low growth in energy use was pooh-poohed by many influential advocates of the status quo, and it received less attention than it deserved.
Friedman, Milton. 1970. "The social responsibility of business is to increase its profits". *New York Times Magazine*, September 13. Argues that as long as businessmen operate within the law, it is an unfair tax on stockholders to devote resources to anything but maximizing profits (neglecting the role businessmen play in determining the passage and administration of those laws).
Fuller, John G. 1975. *We almost lost Detroit*. Reader's Digest Press, New York. Documents how the AEC pressed on with Fermi fast breeder, even though a string of accidents had indicated how little could be predicted about nuclear technologies.
Galbraith, John K. 1967. *The new industrial state*. Signet, New York. A most interesting, logical, and controversial thesis about the nature of the military-industrial-university-government complex.
-----. 1973. *Economics and the public purpose*. Houghton Mifflin, Boston. Calls, possibly in vain, for a reorientation of the concerns of economists.
Gatos, Harry C. Undated. *Materials processing in space*. Statement before Subcommittee on Manned Space Flight, Committee on Science and Astronautics, U.S. House of Representatives. Details the advantages of zero gravity processing.
Georgesçu-Roegen, N. 1971. *The entropy law and the economic process*. Harvard University Press, Cambridge, Mass. An economic analysis beginning with the laws of thermodynamics. Technical. For an amusing contrast, see Richard Zeckhauser, *The risks of growth*.
Godkin, E. L. 1865. "Aristocratic opinions of democracy". *North American Review*, January.
Goeller, H. E., and A. Weinberg. 1976. "The age of substitutability". *Science*, vol. 191, pp.

683-689 (February 20).
Goldsmith, Edward. 1976. "Ecology -- the new political force". *The Ecologist*, vol. 6, no. 9, pp. 310-311. The ecology movement in Europe has evolved into increasingly successful political parties.
Graham, Frank Jr. 1970. *Since silent spring*. Fawcett-Crest, Greenwich, Conn. Details of the pesticide controversies.
Graubard, S. R., ed. 1973. "The no-growth society". *Daedalus*, fall. Several important articles.
Greeley, Fr. Andrew. 1976. *Catholic schools in a declining church*. Sheed and Ward, Mission, Kans. A survey of Catholic attitudes, showing that the decline in church participation among Catholics is largely due to the papal encyclical condemning birth control.
Green, Harold P. 1975. "The risk-benefit calculus in safety determination".

The George Washington Law Review, vol. 43, pp. 791-807. A dissection of an article by Philip Handler, president of the National Academy of Sciences. See Handler, 1975,
Hamilton, W. F., II; and D. K. Nance. 1969. "Systems analysis of urban transportation". *Scientific American*, July. Problem of urban transport and some possible solutions.
Hammond, George S. 1976. "The value system in the scientific subculture". *Bulletin of the Atomic Scientists*, December, pp. 36-40. Perceptive analysis of how pure science has become a new religion.
Handler, Philip. 1975. "A rebuttal: The need for a sufficient scientific base for government regulation". *The George Washington Law Review*, vol. 43, pp. 808-813. A rebuttal to Harold P. Green, The risk-benefit calculus in safety determination. Among other amazing statements, Handler says, "[the charge that] DDT 'can impair reproduction of birds' . . . rests exclusively on the behavior of the brown pelicans of Anacapa Island, which lay in the effluent stream from a factory which manufactured DDT, and it is equally possible that the thinning of eggshell formation in that colony was occasioned by a variety of other external phenomena" (p. 812) (See Chapter 11 here for the diverse evidence that makes his statement nonsense.)
Hardin, Garrett, ed. 1969. *Population, evolution, and birth control*. 2d ed. W. H. Freeman and Company, San Francisco. A fine collection of readings edited by one of the best writers among biologists.
-----, and John Baden, eds. 1977. *Managing the Commons*, W. H. Freenman, San Francisco. A stimulating collection of essays covering social and ethical dimensions of dealing with scarcity and public goods.
Hardmann, M., and P. Manning. 1975. *Green bans*. Australian Conservation Foundation. Describes how workers in Australia have withheld their labor from socially or environmentally undesirable projects.
Harvard Law Review Association. 1971. "Legal analysis and population control: The problem of coercion". *Harvard Law Review*, vol. 84, no. 8, pp. 1856-1911.
Harwood, Robert F. 1975. "Economics, esthetics, environment, and entomologists: the tussock moth dilemma". *Environmental Entomology*, vol. 4, pp. 171-174. Discussion of the decision to lift the DDT ban so it could be used against a tussock moth outbreak in the northwestern United States.
Hayes, Denis. 1971. "Can we bust the highway trust?" *Saturday Review*, June 5, pp. 48-53.

Heffernan, Patrick. 1975. "Jobs and the environment". *Sierra Club Bulletin*, April, pp. 25-30. Gives data supporting the view that "environmental standards and programs, rather than eliminating jobs, are currently significant sources of employment."
Heilbroner, Robert L. 1972. *The worldly philosophers: The lives, times and ideas of the great economic thinkers*. 4th ed. Simon and Schuster, New York. This classic, written by one of the most outstanding and ecologically aware modern economists, is a must for all interested in the development of economic thought.
Heller, Alfred, ed. 1971. *The California tomorrow plan*. Kaufmann, Los Altos, Calif. A classic -- shows how much can be accomplished with low-budget planning.
Heller, Walter, ed. 1968. *Perspectives on economic growth*. Random House, New York. A compendium of the conventional wisdom of economic growth. These views can still be found among economists today, but see E. F. Schumacher, *Small is beautiful: Economics as if people mattered*, for an informed economist's perspective.
Henderson, Hazel. 1974. "The entropy state". *Planning Review*, vol. 2, April/May, pp. 1-4. A fascinating brief article from an outstanding futurist. You might wish to read the profile of Ms. Henderson by Constance Holden in *Science*, vol. 190, pp. 862-864 (November 28, 1975).
Henkin, H.; M. Merta; and J. Staples. 1971. *The environment, the establishment, and the law*. Houghton Mifflin, Boston. An excellent recounting of the landmark DDT hearing in Wisconsin 1968/1969 with much quoted testimony.
Herendeen, R. 1974. "Energy and affluence". *Mechanical Engineer*, October. Shows how direct and indirect energy use vary with income.
Holdren, John P. and Paul R. Ehrlich, eds. 1971. *Global ecology: Readings towards a rational strategy for man*. Harcourt Brace Jovanovich, New York. Reprints Berle's "What GNP doesn't tell us"; Boulding's Economics of the coming Spaceship Earth; and Ehrlich and Holdren's Population and panaceas.
Holdren, John and P. Herrera. 1971. *Energy*. Sierra Club, San Francisco. See discussion of Storm King case and similar battles.
Holliday, Robin. 1977. "Should genetic engineers be contained?" *New Scientist*, February 17, pp. 399-400. Considers chance of disaster very remote on the basis of approximate (and generally conservative) probability calculations.
Hooker, C. A. 1975. "Has the scientist any future in the brave new world?" In *Science and society*, N. Steneck, ed. University of Michigan Press, Ann Arbor, pp. 306-356. See especially the material on the scientific establishment. Useful bibliographic notes.
House, Peter W. 1976. *The quest for completeness: Comprehensive analysis in modeling, indicators, gaming, planning and management*. D. C. Heath and Co, Lexington, Mass. Strategies for long-range, comprehensive planning, incorporating environmental concerns. Contains a useful discussion of measures of quality of life.
-----. 1977. *Trading-off environment, economics and energy: A case study of EPA's Strategic Environmental Assessment System*. D. C. Heath and Co., Lexington, Mass. Discusses a computer-based system for developing long-range analyses of the impacts of energy alternatives -- one ingredient of comprehensive planning.
-----, and J. McLeod. 1977. *Large-scale models for policy evaluation*. Wiley-Interscience, Somerset, N.J.
-----, and Edward R. Williams. 1976. *The carrying capacity of a nation*. Heath and Co., Lexington, Mass. Develops a planning model incorporating environmental resources as well

as labor and capital.
Hueckel, Glenn. 1975. "A historical approach to future economic growth". *Science*, vol. 187, pp. 925-931 (March 14). Dramatizes the need for training economists in history and environmental sciences.
Illich, Ivan. 1970. *Celebration of awareness*. Doubleday, Garden City, N.Y. Brilliant critique of social institutions by one of today's most imaginative thinkers.
-----. 1973. *Tools for conviviality*. Harper and Row, New York. A devastating critique of society. Illich argues, "survival in justice is possible only at the cost of those sacrifices implicit in the adoption of a convivial mode of production and the universal renunciation of unlimited progeny, affluence, and power on the part of both individuals and groups."
-----. 1974. *Energy and equity*. Harper and Row, New York. Another critical work by a man who has been described as the twentieth century's leading Luddite.
-----. 1976. *Medical nemesis: The expropriation of health*. Random House, New York. A hard-hitting critique, claiming, among other things, that the medical system has convinced people "society has a supply of health locked away that can be mined and marketed." Highly recommended.

Istock, Conrad E. 1971. "Modern environmental deterioration as a natural process". *International Journal of Environmental Studies*, vol. 1, pp. 151-155. A concise and important article that should be read by all economists.
Johnson, W. R. 1973. "Should the poor buy no growth?" *Daedalus*, fall, pp. 165-189. Suggests that alliances of the very poor and the middle class to wrest more from the super-rich hold the best hope for more equity.
Kahn, H., and A. J. Wiener. 1967. *The year 2000*. Macmillan, New York. A monument to the technological optimists' inability even to come close in forecasting the future. The words ecology, environment, and pollution do not appear in the index -- and Japan is seen as a potential superpower!
Kantrowitz, Arthur. 1975. "Controlling technology democratically". *American Scientist*, vol. 63, pp. 505-509. Proposes the use of scientific advocates before scientific judges to settle scientific aspects of policy disputes.
Katchadourian, H., and D. Lunde. 1975. *Fundamentals of human sexuality*. 2d ed. Holt, Rinehart and Winston, New York. A superb treatment by two psychiatrists, easy to read and authoritative.
Kelso, L. O., and M. J. Adler. 1958. *The capitalist manifesto*. Random House, New York. The original exposition of Kelso's theory of universal capitalism, a proposal for capitalist rather than socialist redistribution of wealth.
Kelso, L. O., and P. Hetter. 1967. *Two-factor theory: The economics of reality*. Random House, New York. A revolutionary book by capitalists. The authors point out that fewer than I percent of United States households are capitalist and set out proposals to change all that.
Kozol, Jonathan. 1967. *Death at an early age*. Houghton Mifflin, Boston. A devastating examination of one of our educational system's major failures.
Landau, N. J., and P. G. Rheingold. 1971. *The environmental law handbook* Ballantine, New York. How to fight pollution in the courts.
Lecomber, Richard. 1975. *Economic growth versus the environment*. Wiley, New York, A brief, informative book, Those unfamiliar with elementary economics will need to read it

with a basic economics text like Paul A. Samuelson, *Economics* at hand.
Leonard, George B. 1968. *Education and ecstasy*. Delacorte, New York. A most thoughtful and original book on education.
Lewis, R. 1972. *The nuclear power rebellion: Citizens versus the atomic industrial establishment*. Viking, New York. A history of the Atomic Energy Commission and the Joint Committee on Atomic Energy, emphasizing controversies and conflicts with independent scientists and citizen groups.
Lichtenberg, A. J., and R. D. Norgaard. 1974. "Energy policy and the taxation of oil and gas income". *Natural Resources Journal* vol. 14, pp. 501-518. Discusses the depletion allowance, foreign tax credits, and other aspects of tax treatment of the oil industry.
Lindsey, Robert. 1975. "Mass transit, little mass". *New York Times Magazine*, October 19. If cars remain unrestricted and gasoline cheap, mass transit won't help much with congestion or energy conservation.
Loebl, Eugen. 1976. *Humanomics: How we can make the economy serve us -- not destroy us*. Random House, New York. A critique of standard capitalist and Marxist economics by a professor of economics who has served in several key economic positions in communist Czechoslovakia. He starts from the premise, "Conventional economics has become, despite its remarkable degree of sophistication, not only a useless tool, but a dangerous one. Its deceptive application has created a crisis which threatens the very foundation of our civilization."
Lundberg, Ferdinand. 1968. *The rich and the super-rich* Bantam, New York. An eye-opening book for those bedazzled by "people's capitalism" and the high-school-civics-class versions of how our government functions.
McCaull, Julian. 1976. *Energy and jobs, Environment*, January/February, pp. 18-20. Reports on relationship of energy use to employment.
Macrae, Norman. 1975. "America's third century". *The Economist*, October 25. Read this to discover what happens when an economist "raid(s) the fertile mind of Herman Kahn."
Maddox, John. 1972. *The doomsday syndrome*. McGraw-Hill, New York. A curious mixture of incompetent analysis and technology-asreligion. Maddox has great faith in the rationality of the scientificindustrial system. For a refutation, see Ehrlich and Holdren, "The hysteria against the case"; and John Woodcock, "Doomsday revisited".
Margolis, Joseph. 1971. *Values and conduct*. Oxford University Press, New York. An important book by a well-known ethical theorist -an introduction to moral philosophy.
Marx, Leo. 1970. "American institutions and ecological ideals". *Science*, vol. 170, pp. 945-952 (November 27). A thoughtful discussion of the profound changes in our institutions that really cleaning up the environment will require.
Mayle, Peter. 1973. "Where did I come from?" Lyle Stuart, Secaucus, N.J. Good book for preteens on sex and reproduction.
Means, Richard L. 1970. *The ethical imperative: The crisis in American values*. Doubleday, Garden City, N.Y. Excellent.
Medvin, N. 1974. *The energy cartel*. Random House, New York. Useful for the history of vertical and horizontal integration of the United States energy industry.
Meier, Richard L. 1976. "A stable urban ecosystem". *Science*, vol. 192, pp. 962-968 (June 4). A vision of stationary population and resourceconserving cities.
Metzger, P. 1972. *The atomic establishment*. Simon and Schuster, New York. Well written critical history of the Atomic Energy Commission and the Joint Committee on Atomic

Energy.
Miller, M. G. 1975. "The case for water transport". *Ecologist*, vol. 5, pp. 259-261. "A waterway can carry freight more economically than the equivalent area of road or rail, causing less disruption to the environment, using less energy and generating less pollution."
Mintz, M., and J. S. Cohen. 1971. *America, inc.: Who owns and operates the United States*. Dial, New York. A very important book dealing with the evils of concentrated economic power and possible ways of diffusing it. See especially the material on big oil companies, and then think about events since the book was published.
Mishan, Ezra J. 1970. *Technology and growth: The price we pay*. Praeger, New York. A more popular version of The costs of economic growth.
-----. 1973. "Ills, bads, and disamenities: The wages of growth". *Daedalus*, vol. 102, no. 4 (Fall), pp. 63-87.
Moncrief, Lewis W. 1970. "The cultural basis for our environmental crisis". *Science*, vol. 170, pp. 508-512 (October 30).
Montefiore, Hugh. 1975. "Population control: An ethical and theological perspective". *International Journal of Environmental Studies*, vol. 8, pp. 53-58. A worthwhile discussion, giving insight into the moral concerns of a well informed Anglican bishop.
Montgomery, Johnson C. 1971. "The population explosion and United States law". *Hastings Law Journal*, vol. 22, no. 3, pp. 629-659. First definitive treatment of this subject.

Moore, Gerald, 1976. "Legal aspects of marine pollution control". In R. Johnston , ed., *Marine pollution*, Academic Press, New York, pp. 589-679. Examines international level and controls at the national level in the USA and UK. Detailed and highly documented.
Moss, Elaine, ed. 1976, "Land use controls in the United States". Dial Press for the Natural Resources Defense Council, New York. A handbook for public-interest groups.
Mostert, Noel. 1974. *Supership*. Knopf, New York. Well written description of the economics and hazards of these giant ships.
National Academy of Sciences (NAS). 1976. *Study on problems of pest control*. NAS, Washington, D.C. One of the best efforts of the NAS. Deals with many of the economic and political aspects of the functioning of the pesticide system. See especially volume 1, Contemporary pest control practices and prospects.
Nelson, L. D., and Julie A. Honnold. 1976. "Planning for resource scarcity: A critique of prevalent proposals". In C. M. Bonjean, ed., *Scarcity and Society* (*see*Recommended Reading). Claims various proposals, such as educational reform and long-term planning, made by the authors of this book and other environmentalists, may be dangerous. The environmentalists' proposals may delay movement to systems of sanctions social scientists think are necessary. An important paper.
Nicholson, Max. 1976. "The ecological breakthrough". *New Scientist*, November 25, pp. 460-463. A history of the development of ecology, once an obscure branch of "pure" science, into a subject of worldwide political importance. The focus is on the U.K., long a leading center of professional ecology.
Nordhaus, William, and James Tobin. 1972. "Is growth obsolete?" *Fiftieth Anniversary Colloquium, National Bureau of Economic Research*, Columbia University, New York. A thoughtful article within the traditional economic paradigm, attempting to produce a measure for economic welfare (MEW). Environmentalists should read this. (See also Arthur M. Okun, "Social welfare has no price tag".)

O'Brien, Fr. John A., ed. 1968. *Family planning in an exploding population*. Hawthorne, New York. Statements by scholars within and outside the Catholic church, edited by an outstanding Catholic theologian who has strongly disagreed with that church's stand on birth control.
Ogilvie, J., and B. Johnson. 1975. "Railways: Accounting for disaster". *New Scientist*, October 23. Economics of British railways-well done.
Okun, Arthur M. 1971. "Social welfare has no price tag". *Survey of Current Business*, July, pp. 128-133. Speaking against revision of the GNP, the author says it never has and never will measure social welfare and warns against attempts to formulate alternatives like that of Nordhaus and Tobin (above).
Olson, M.; H. H. Landsberg; and J. L. Fisher. 1973. "Epilogue". *Daedalus*, fall, pp. 224-241. Even though we disagree to some extent, this is interesting reading on the no-growth society.
O'Neill, Gerard K. 1974. "The colonization of space". *Physics Today*, September. The original article on space colonies.
-----. 1975. "Space colonies and energy supply to the Earth". *Science*, vol. 190, pp. 943-947 (December 5). Describes construction of satellite solar-power stations by a space manufacturing facility.
-----. 1977. "The high frontier: Human colonies in space". Wm. Morrow, New York. Details O'Neill's space-colony scheme. Fascinating reading.
Ophuls, William. 1973. *Prologue to a political theory of the steady-state*. Ph.D. Dissertation, Yale University. Integrates political theory and environmental concerns; excellent.
-----. 1977. *Ecology and the politics of scarcity*. W. H. Freeman, San Francisco. A useful, well-argued text, covering the nature of the environmental predicament and a political scientist's perspective on solutions.
Owen, Henry, and Charles L. Schultze, eds. 1976. *Setting national priorities: The next ten years*. Brookings Institution, Washington D.C. One in a series of volumes with this title, published annually by Brookings since 1970. Most deal rather narrowly with the annual federal budget, but this one takes a longer view of issues in defense, inflation, interdependence, energy, environment, and other issues touched by the budget but in need of longer-range, more systematic planning.
Page, S., Jr., and W. Clark. 1975. "The new alchemy: How to survive in your spare time". *Smithsonian*, February, pp. 82-88. Describes the activities of the New Alchemy Institute, focused on small-scale, low-energy, and nonchemical farming.
Parsons, Jack. 1975. "The economic transition". *Conservation Trust*. The ultimate demolition of the main myths of growth.
-----. 1977. *Population fallacies*. Elek/Pemberton, London. A penetrating analysis of fallacies concerning population growth and its relationship to socio-economic and other factors.
Patterson, Walter C. 1976. *Nuclear power*. Penguin, Baltimore. A fine overview for the layman with an especially useful and clear discussion of the complexities of reactor technology.
Pearson, D., and J. Anderson, 1968. *The case against Congress*. Simon and Schuster, New York. Pre-Watergate description of the mess in our legislation. Much is still pertinent in the late 1970s.

Peterman, W. A. 1974. "The myth of Amtrak". *Environment*, vol. 16, November.
Pirages, Dennis C. 1975. "The unbalanced revolution". In *Science and Society*, N. H. Steneck, ed. University of Michigan Press, Ann Arbor, pp. 231-249. Discusses bringing science back under the control of society.
-----, ed. 1971. *Seeing beyond: Personal, social and political alternatives*. Addison-Wesley, Reading, Mass. A fine collection of readings bringing together a wide variety of articles dealing with contemporary human problems.
-----ed. 1977. *The sustainable society. Social and political implications*. Praeger, New York. A useful collection of articles, combining technological, economic, and political viewpoints.
Platt, John. 1969. "What we must do". *Science*, vol. 166, pp. 1115-1121 (November 28). A classification of the urgency of our multiplicity of crises and suggestions on how we might meet them.
Post, R. F., and S. F. Post. 1973. "Flywheels", *Scientific American*, December, pp. 17-23. On one mode of conserving energy in transportation.
Primack, Joel, and Frank von Hippel. 1974. *Advice and dissent*. Basic Books, New York. A readable discussion of the role of scientists in the political arena. Case studies include the SST, the antiballistic missile, pesticides, chemical and biological warfare, and nuclear power.
"Resources for the Future". 1968, *U. S. energy policies: An agenda for research*. Johns Hopkins Press, Baltimore. Although a little out-ofdate, this book offers a useful compilation of information on state and federal policies regarding coal, oil, gas, and uranium since 1930.
Roddewig, R., and J. S. Rosenberg. 1975. "In Australia, unions strike for the environment". *Conservation Foundation Letter*, Washington, D.C., November. On the green bans against environmentally

damaging projects.
Rostovtzeff, Mikhail. 1941. *Social and economic history of the Hellenistic world* 3 vols. Oxford University Press, New York.
Russell, Bertrand. 1945. *A history of western philosophy*. Simon and Schuster, New York. A classic by one of the greatest thinkers of the twentieth century. See especially the material on anthropocentrism.
Sahlins, Marshall. 1972. *Stone age economics*. Aldine, Chicago. Primitive people had few possessions but were not poor: ". . . it was not until culture neared the height of its material achievements that it erected a shrine to the Unattainable: Infinite Needs."
Samuelson, Paul A. 1976. *Economics*. 10th ed. McGraw-Hill, New York. The standard economics text.
Schipper, Lee. 1976. "Raising the productivity of energy use". *Annual Review of Energy*, vol. 1, pp. 455-517. Well-documented discussion of potential for increasing employment and real economic well-being through saving energy.
Schneider, S. H., and L. E. Mesirow. 1976. *The genesis strategy*. Plenum, New York. Contains some useful ideas on the science-policy interface.
Serling, Robert J. 1960. "The probable cause". Doubleday, Garden City, N.Y. Somewhat out-of-date but still interesting description of aviation accidents in the golden age of prop transport.
Sessions, George S. 1974. "Anthropocentrism and the environmental crisis". *Humboldt Journal of Social Relations*, vol. 2, pp. 1-12. Overview with good bibliography.

Sierra Club Bulletin. 1975. "The green ban". April, pp. 18-19. On the actions of organized labor against environmentally damaging projects in Australia.
Sinsheimer, Robert. 1975. "Troubled dawn for genetic engineering". *New Scientist*, October 16, pp, 148-151. Contains a good summary of the technology, risks, and benefits of recombinant DNA experiments.
-----. 1977. "An evolutionary perspective for genetic engineering". *New Scientist*, January 10, pp. 150-152. A distinguished biologist expresses concern that National institutes of Health guidelines for recombinant DNA research are "too narrowly conceived" and "inadequate."
Skinner, B. F. 1971. *Beyond freedom and dignity*. Knopf, New York. Skinner finally says it in terms understandable even to those who have not followed his work -- individuals can neither be blamed for their failures nor credited with their accomplishments. The book caused an uproar even before publication. Must reading, even if you disagree.
Spengler, Joseph J. 1960. "Population and world economic development". *Science*, vol. 131, pp. 1497-1502 (May 20). Old but worthwhile.
Steinhart, J., and C. Steinhart, 1974. *Energy*. Duxbury, North Scituate, Mass. An outstanding introductory text on technology, environmental impact, and policy.
Steneck, N. H., ed. 1975. *Science and society*. University of Michigan Press, Ann Arbor. A diverse collection -- see especially the articles by Pirages, Cottle, Hooker, and Toulmin.
Stockholm International Peace Research Institute (SIPRI). 1976. "Why arms control fails". *Atlas World Press Review*, February, pp. 11-13. Statistics on numbers of scientists involved in war research (about half of them).
Stone, Tabor R. 1971. *Beyond the automobile. Reshaping the transportation environment*. Prentice-Hall, Englewood Cliffs, N.J. An interesting book that explores some new directions for transportation in the United States.

Woodward, Herbert. 1976. *Capitalism can survive in a no-growth economy*. Brookdale/Walker, Stamford, Conn. Argues cogently that it can survive and thrive. Well worth reading.
Zeckhauser, Richard. 1973. "The risks of growth". *Daedalus*, vol. 102, no. 4, pp. 103-118. An article noteworthy only because it shows how ignorance of the physical world can warp an economist's conclusions. Zeckhauser shows he is unfamiliar with the second law of thermodynamics by his statement (p. 117), "Recycling is not the solution for oil, because the alternate technology of nuclear power generation is cheaper."

CHAPTER 15
Rich Nations, Poor Nations, and International Conflict

A planet cannot, any more than a country, survive half slave, half free, half engulfed in misery, half careening along toward the supposed joys of almost unlimited consumption. Neither our ecology nor our morality could survive such contrasts. And we have perhaps ten years to begin to correct the imbalance and to do so in time.

-- Lester Pearson, 1969

Throughout this book we have been referring to developed and less developed countries -- the rich and the poor nations -- because this is the fundamental division of humanity today. In our view, it supersedes the more recognized political-economic division between capitalism and communism. The growing gulf between rich and poor nations is fairly recent. For most of the history of industrial civilization (and before), there was a continuum from the poor to the rich; and most nations and their peoples were poor. Then, as geochemist Harrison Brown of the California Institute of Technology described it, since World War II, "a striking pattern has evolved amounting to no less than a fissioning of human society into two quite separate and distinct cultures -- the culture of the rich and the culture of the poor, with very few people living in between these two extremes." [1] That fissioning between nations can be seen quite clearly, for example, in trends of per-capita energy consumption and per-capita steel consumption (see Figure 15-1). But many other differences exist, most of which have been enumerated in previous chapters: rates of population growth; levels of nutrition, health, education, and general well-being.

If current trends were to continue, by the year 2020 there would be about 10.5 billion people, of whom 1.4 billion would be rich, 8.5 billion poor, and 0.6 billion in

[1]Population growth and affluence: The fissioning of human society.

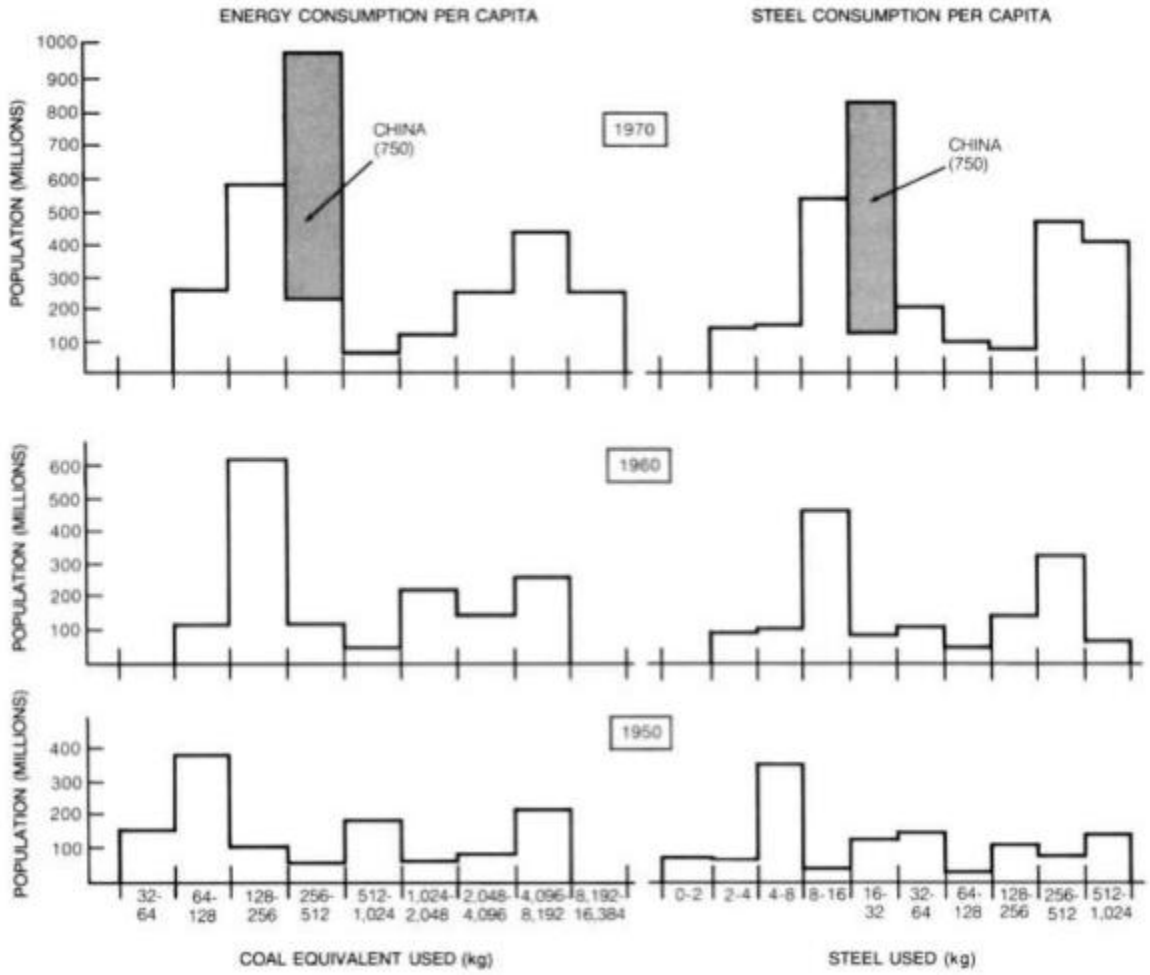

FIGURE 15-1 The evolution of the rich-poor gap in the use of energy and materials. Note that information on China was available only for 1970. (From H. Brown, 1975.)

between. The ratio of the per-capita energy consumption between the rich and the poor would have climbed from 20.5 to 39.9-that is, the gap would virtually have doubled. The environmental implications of such an overall rate of energy consumption are discussed in Chapter 8, but there would be grave political implications as well. If the world were to continue on that route, it is not unlikely that much of the energy used would be generated by nuclear power plants. As Brown warned, "The potential instabilities in a system composed of an affluent minority coexisting with a crowded, hungry, and discontented majority, which has access to nuclear fuels, are awesome to contemplate." [2]

The consequences of the gap between rich and poor nations, and possibilities for healing it before it leads to a nuclear Armageddon, are the basic subject of this chapter. It is vital to avoid the awesome situation Brown described, and the urgency is great since the international situation

grows more threatening daily. Before considering corrective action, however, we examine some of the elements of the existing situation, with particular con-

[2] ibid., p. 242.

sideration of why, after nearly two decades of effort to develop poorer nations, most of them are even poorer than before in comparison with the rich nations.

RICH WORLD, POOR WORLD

In recent years a widely used international taxonomy has developed by which politicians could avoid using such descriptive terms as *the poor nations, the have-nots*, or as one historian put it (sadly, but perhaps accurately), *the ain't-gonna-gets*. The code [3] classifies nations into various "worlds."

1. The First World: These are the noncommunist DCs, such as Australia, Denmark, Japan, Portugal, the United Kingdom, the United States, and West Germany. Many, but not all, are democracies. Economically also, the First World is a mixed bag. Portugal, although rich compared to Haiti, is poor compared to the United States. The United Kingdom still had a high per-capita income in 1976, but its economic prospects were bleak; and although Japan was doing better than the UK, its long-term prospects were dreadful. [4]

2. The Second World: This is the group of the communist countries -- another mixed bag, including Albania, China, Cuba, North Korea, Poland, the USSR, and Yugoslavia, among others. Some -- the USSR and most eastern European countries -- are highly industrialized; the Asian communist countries and Albania are not.

3. The Third World: These are the poor nations thought by some to have a chance of getting rich, or at least of developing to a substantial degree without a great deal of external aid, generally because of their resource bases. The group includes the Organization of Petroleum Exporting Countries (OPEC), Argentina (agricultural products), Malaysia (lumber, rubber, tin), Morocco (phosphates), Zaire (copper), Zambia (copper), and countries like Brazil, Mexico, Taiwan, and South Korea, which have attracted outside capital and which have relatively well-developed industries. The prospects of many of these nations hinge on how effectively they can institute population control; that of Brazil is also heavily tied to whether it ceases the destruction of Amazonia before it is complete. [5]

4. The Fourth World: This is a group of LDCs that might become economically self-sustaining with moderate outside help. It includes Colombia, Egypt, Ghana, India, Indonesia, Peru, the Philippines, Turkey, and Vietnam.

5. The Fifth World: These are the international "basket cases" -- nations that for the foreseeable future can only persist with substantial outside aid. They have difficulty feeding themselves and have little to offer for export. Grossly overpopulated Bangladesh is the largest, but others include Chad, Ethiopia, Guinea, Somalia, Rwanda, and Upper Volta. They are generally characterized by extreme poverty; several are in the Sahel region of Africa that was disastrously stricken by drought between 1968 and 1975. Most of the thirty-two nations listed by the United Nations in 1974 as most in need of help are in this category.

In some classifications, the Third and Fourth worlds are lumped into the Third World, and the Fifth World is called the Fourth. [6] Occasionally, an older classification is used in which all LDCs

(including China) are called the Third World. Sometimes *North* and *South* or *highincome* and *low-income* are used as synonyms for *rich* and *poor*. [7]

Whatever classifications are used, it should be remembered that the key divisions are based on wealth and that most persons live in countries and in circumstances that, compared with the United States, can only be considered poor. In 1973, 61 percent of the world's population lived in countries where per-capita annual incomes were less than $500, [8] and 20 percent had less than $50 income per person. In contrast, fewer than 10 percent lived in countries where per-capita incomes were greater than $5000, and more than half of those were Americans.

TABLE 15-1 Income Distribution Within Selected Less Developed and Developed Countries

	Percentage of national income received by population groups				
	Richest 20%	**Second 20%**	**Third 20%**	**Fourth 20%**	**Poorest 20%**
LESS DEVELOPED COUNTRIES					
Argentina (1961)	52.0	17.6	13.1	10.3	7.0
Ecuador (1970)	73.5	14.5	5.6	3.9	2.5
Egypt (1964-1965)	47.0	23.5	15.5	9.8	4.2
India (1963-1964)	52.0	19.0	13.0	11.0	5.0
Kenya (1969)	68.0	13.5	8.5	6.2	3.8
Korea, Rep. of (1970)	45.0	22.0	15.0	11.0	7.0
Mexico (1969)	64.0	16.0	9.5	6.5	4.0
Sri Lanka (1969-1970)	46.0	20.5	16.5	11.0	6.0
Tanzania (1967)	57.0	17.0	12.0	9.0	5.0
DEVELOPED COUNTRIES					
Australia (1967-1968)	38.7	23.4	17.8	13.5	6.6
France (1962)	53.7	22.8	14.0	7.6	1.9

	Percentage of national income received by population groups				
	Richest 20%	**Second 20%**	**Third 20%**	**Fourth 20%**	**Poorest 20%**
Germany, Dem. Rep. (1970)	30.7	23.3	19.8	15.8	10.4
Germany, Fed. Rep. (1970)	45.6	22.5	15.6	10.4	5.9
Hungary (1967)	33.5	23.5	19.0	15.5	8.5
Japan (1968)	43.8	23.4	16.8	11.3	4.6
Sweden (1970)	42.5	24.6	17.6	9.9	5.4
United Kingdom (1968)	39.2	23.8	18.2	12.8	6.0
United States (1970)	38.8	24.1	17.4	13.0	6.7

Notes: Income distribution data are incomplete and deficient, and inter-country comparisons should be made with caution. A completely equal distribution of national income would show the richest 20 percent and the poorest 20 percent of the population (as well as all other quintiles) each receiving 20 percent of that country's income.

Source: J. W. Sewell, ed. *The United States and World development agenda*, 1977. Overseas Development Council, Praeger, New York.

Sixty-seven percent of the world's wealth is controlled by 17 percent of the population.

The statistics on disparities in *average* incomes between rich countries and poor countries, as shocking as they are, do not reveal the true magnitude of the rich-poor gap. That magnitude becomes fully apparent only when the uneven distribution of income *within* countries is taken into account. The nature of this distribution in most countries is such that a great many people have incomes far below the average. Income distributions for 44 LDCs around 1970 are shown in Table 15-1.

The growing disparity in wealth and access to high living standards has not gone unnoticed by the poor majority. Not only is this gap now the most significant economic division between nations, it is rapidly becoming a political issue of overwhelming importance. Defusing the rich-poor confrontation may be humanity's most urgent political task in the next decade or two.

Trade and Foreign Aid: An International Shell Game

Inequality and injustice within countries are matched only by inequality and injustice between countries. These are the two obscenities of world development. And they are obviously linked.

-- Louis Emmerji, *Director of the World Employment Programme, International Labour Organization, 1975*

When one reads the literature on DC-LDC relationships -- especially that dealing with the economic aspects -- it is sometimes difficult to believe that the writers are all describing the same situation. Consider the question of whether developed countries exploit LDCs (or, as is often stated, do the DCs practice neocolonialism or economic imperialism?). On one side, in connection with the extraction of raw materials from LDCs, econ-

omist Ansley Coale in 1970 declared: "The most effective forms of assistance that the developed countries (including the United States) give to the less developed countries are the purchases they make from the less developed countries in international trade." [9]

On the other hand, socialist economist Pierre Jalée wrote in 1968 that LDCs "are not poor because of a curse of nature, that they are not lacking in natural wealth, least of all in raw materials for heavy industry. They are poor only because . . . this natural wealth has been, and still is being, plundered by imperialism for the needs of its own industrialization, at the expense of those countries from which it flows away in its raw state." [10]

Which, if either, of these views is correct?

It is quite true that great damage would be done to LDC economies if DCs reduced their purchases of commodities. LDC economies have been set up to supply commodities to DCs, and generally are not in a position to use those commodities themselves. But one must question why less developed nations are in such a position; that is, what historical events channeled their economic development into such narrow pathways? One must also ask who or what determines the prices paid for the commodities? And, perhaps most important, one must ask who (that is, what group) within an LDC benefits from the trade in commodities? Is it the mass of the people or is it a small ruling elite? If the latter, are the DC commodity consumers in any way involved in keeping those elites in power? No special economic expertise is needed to find a partial answer to these questions.

The shortcomings of the Coale position do not, however, wholly validate Jalée's. There is no reason to believe that present-day LDCs would have developed their natural wealth by now if it were not for the rapacious interference (or at least influence) of the DCs. The cultural conditions for an Industrial Revolution were hardly universal. After all, the Chinese did not undergo such a revolution even though they were civilized long before western Europe. Nor did the Arabs, who also possessed a rich civilization, find or utilize their vast oil resources. Without the stimulus of Western resource-tapping and the example of Western materialism, would the Third World even be interested in industrial development or its presumed fruits?

The truth is probably closer to Jalée's view than Coale's. Whether or not the LDCs would eventually have found and utilized their resources for themselves, with or without nonexploitive help from DCs, is beside the point. In recent years the resource flow has been predominantly from LDCs to DCs. The rich have been getting steadily richer and most of the poor have been lucky to stay even.

A third view of the situation presented by writer Tom O'Brien seems to us more accurate than that of either Coale or Jalée:

I am not suggesting the underdevelopment of the Third World is a result of intentional efforts by the developed world, but neither is it the result of misguided benevolent intentions leading to unintentionally negative results. The intention of capital is profit, which, even when it includes the benevolent belief that profit-for-some can be profit-for-all, nevertheless means without some political mechanism for redistribution, an ever-widening gap between those who have more capital and those who have less. There has been no conscious conspiracy to depress the Third World; the unconscious operation of the market has been enough. [11]

In view of the comparatively great wealth of the developed nations, there should be a great deal the United States and other affluent nations might do to help improve conditions for people in the less developed world. To date, however, the rich world has generally done more to worsen the situation of the poor than to improve it -- and the United States has been a leader in that performance, despite its record of foreign assistance.

Since World War II, United States economic interests have expanded to the far corners of Earth, investing many billions of dollars to develop a trade network designed to serve our national self-interest. Like other powerful nations, the United States has consistently used economic, political, and military means to maintain this trade network. American foreign-aid programs have been far more economic and political in orientation than humanitarian (despite the beliefs of most Americans that

---

[10] *The pillage of the Third World*.
[11] Marrying Malthus and Marx.
[9] Man and his environment.

the programs were selfless); American resources have been devoted mainly to providing additional material goods for ourselves and to an expensive and dangerous arms race, rather than to improving the lot of our fellow human beings.

Latin America and the United States: Problems of Paternalism

The pattern of relationships among DCs and LDCs prevailing until recently is exemplified by the behavior of the United States toward Latin America in this century. The United States has long claimed a special relationship with its neighbors to the south, but this more often than not has meant a desire for exclusive exploitation rights. The one-sidedness of the agreement has not gone unnoticed by Latin Americans.

When Sol Linowitz resigned in 1969 as U.S. ambassador to the Organization of American States, he warned of the possibility of "a series of Vietnams" in Latin America. The same year Nelson A. Rockefeller, then governor of New York, was sent on a fact-finding tour south of the border for President Nixon. He was greeted with a violence that underlined the Linowitz warning.

Rockefeller was, of course, an especially ironic choice since his family's association with Standard Oil is so much a symbol of U.S. economic imperialism. But one does not have to look far for more fundamental reasons for his hostile reception.

Population growth in Latin America was proceeding at an average of 2.9 percent per year during the first eight years of the Alliance for Progress, while per-capita economic growth only averaged about 1.5 percent per year, a full percentage point below the Alliance target. A large portion of the Latin American population was then -- and still is -- for the most part living in appalling poverty. For millions, diets were inadequate, infant and child mortality sky-high, and decent housing often nonexistent. If 10,000 houses had been built per day in Latin America between 1969 and 1979, something on the order of 100 million of our southern neighbors (more than one-fourth of the expected population there) would still not be adequately housed. Although land reform has begun in some countries -- most recently in Peru -- 10 percent of the people in Latin America still owned 90 percent of the land in 1976. And in most Latin American countries, progress toward an equitable distribution of income has been slow, especially for the rural populations.

Development in most of Latin America has scarcely touched the poor. The rich-poor gap has widened in many countries, especially the richer ones such as Brazil and Mexico, and national economies have tended to become two-tiered. The upper tier consists of large landholders and the urban upper and middle classes, especially in such industrial centers as São Paulo and Mexico City. In the lower tier are the urban poor and peasants, bypassed by modernization. In Mexico City, for example, a skilled worker in 1976 earned more than $500 a month, including benefits. But outside the city, minimum wages for farm workers were $5 a day, and because of underemployment many earned as little as $100 per year. [12]

In several countries, notably Brazil, Peru, and Paraguay, there is a third, even lower tier -- primitive Indians, who are being systematically exterminated as roadblocks in the path of progress. In Paraguay, which is heavily under U.S. influence, there have been charges of United States Central Intelligence Agency (CIA) complicity in those programs. [13] True or not, that such charges are widely believed south of the border says something about U.S.--Latin American relations.

Latin America's political instability is legendary (Figure 15-2). Between 1961 and mid-1976 political changes were made by military force in Argentina, Bolivia, Brazil, Chile, Dominican Republic, Ecuador, El Salvador, Guatemala, Honduras, Panama, and Peru -- in some countries more than once. This political turmoil cannot all be blamed on the United States, but American behavior in Latin America has done little to foster stability there. Although the days when United States corporations directly controlled small countries are over, a huge reservoir of ill will remains from those days, when those corporations openly took what they wanted of the mineral and agricultural wealth of the continent. This

---

[12] A no-nonsense mood takes hold in Mexico, *U.S. News and World Report*, June 21, 1976, pp. 63-66. For a description of the situation in Brazil, see Robert Harvey, *Brazil: The next nuclear power?*

[13]John Hillaby, *Genocide in Paraguay*.

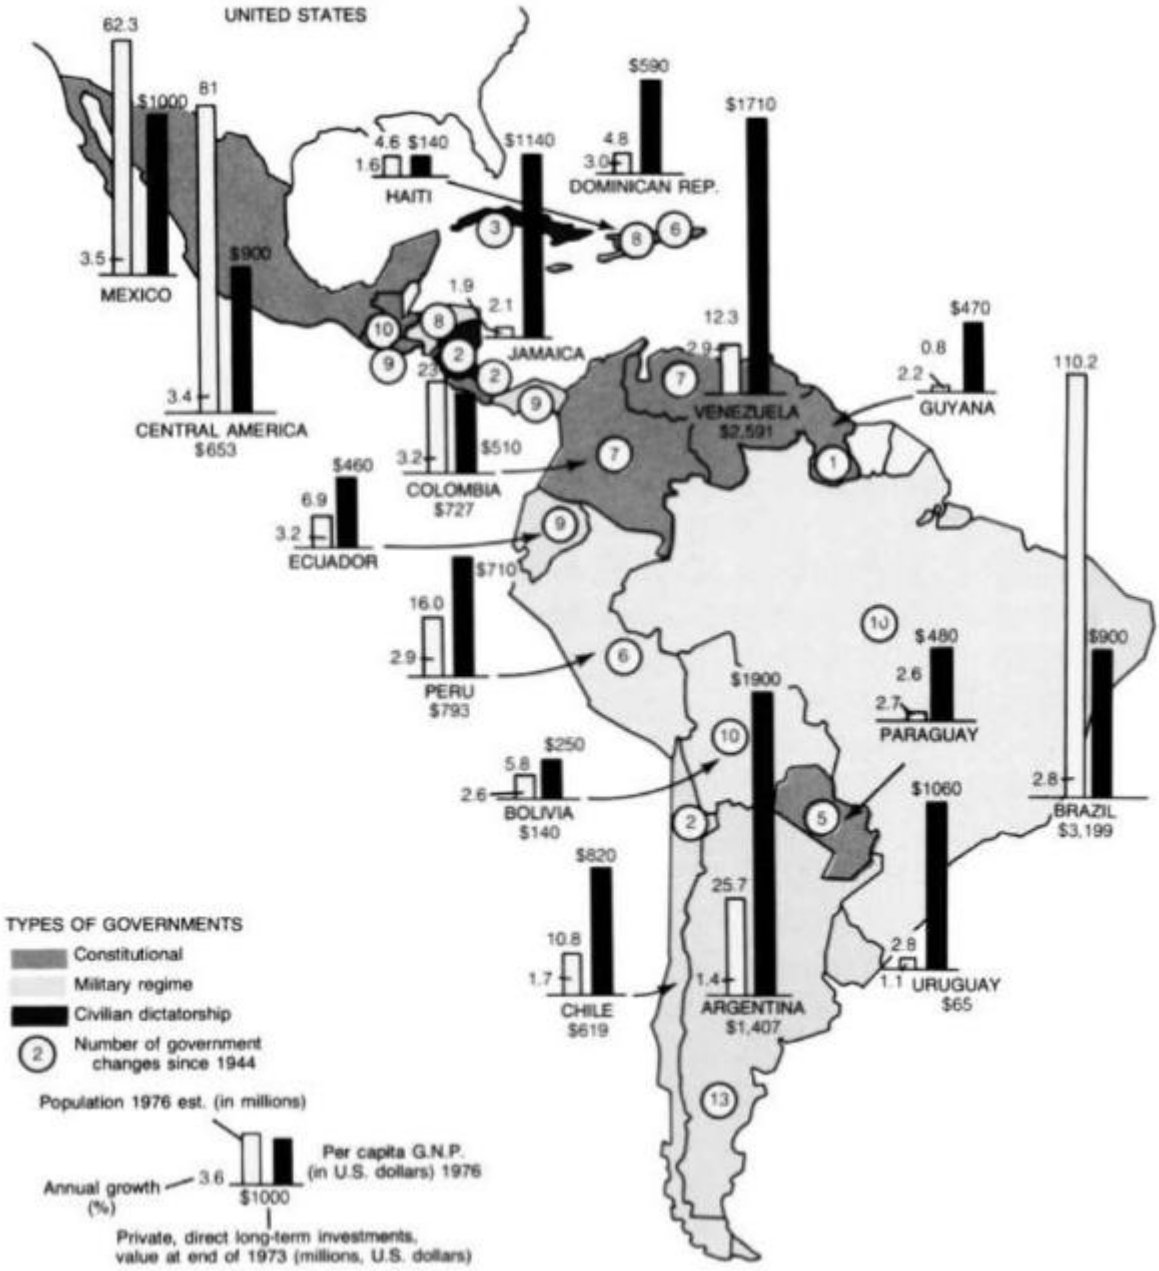

FIGURE 15-2 Latin American summary: population, per-capita gross national product, amounts of American investment, forms of government, and numbers of government changes since 1944 (excluding those resulting from elections, unless they have been interspersed with coups).

widespread resentment was deepened by revelation of CIA involvement in Chile before the 1974 coup that overthrew the Allende government in Chile. Moreover, North American economic exploitation of Latin America is even now far from finished. While some United States multinational companies are now so well-behaved that they can serve as examples of

benevolence, having made significant contributions to their host nations, they still drain vast amounts of natural-resource capital from those nations. And the actions of some other United States multinational firms have had dramatically undesirable effects, especially on the poorest segments of the populations. [14]

[14] For example, see R. J. Barnet and R. E. Müller, *Global reach: The power of the multinational corporations*, chapter 7; and Robert J. Ledogar, *Hungry for profits: U.S. food and drug multinationals in Latin America*.

Since World War II, Latin American attitudes on DC-LDC relationships have been deeply influenced by the United Nations Economic Commission for Latin America (ECLA), and especially by one man, Dr. Raúl Prebisch of Argentina. Prebisch directed ECLA from 1950 to 1962 and became probably the best known economist in the LDCs in 1964 when he chaired the first meeting of UNCTAD (the United Nations Conferences on Trade and Development). Prebisch in 1950 promulgated the idea that the trade relations between DCs and LDCs were not working in favor of the LDCs as classical theory claimed, but *against* the LDCs. [15] He contended that the long-range terms of trade would always favor industrial over agricultural products and proposed a series of remedial steps including development of industrial capacity to manufacture products that traditionally had been imported. The Prebisch thesis that the rich exploit the poor through unfavorable conditions of trade has become a given in the approach of Latin Americans in their dealings with the United States -- and indeed in the views of informed people in most of the less developed world toward the developed world.

In 1969, Latin American governments, meeting at Viña del Mar, Chile, presented a program for improving economic relations with the United States. They requested the United States to lower tariff barriers against Latin American goods and asked for a preferential market for their manufactured products. Basically, they were seeking redress for the economic imbalance in which Latin America still gave the United States more than it received in return. American aid to Latin America amounted to $11 billion in the first eight years of the Alliance for Progress. But profits extracted by U.S corporations operating in Latin America, interest on loans, and arrangements in which aid funds were required to be spent for goods on the expensive markets in the United States (and shipped on U.S. ships) more than compensated for the aid.

Following Viña del Mar and Governor Rockefeller's 1969 trip, there was disappointingly little change in U.S. policies toward Latin America. Rockefeller recommended establishment of more equitable economic relations, to be fostered through tariff changes and other means, and abandonment of the policy of economic "punishment" for governments that nationalized such local industries as copper without satisfactorily compensating the United States companies that had developed them (known as the Hickenlooper amendment). Rockefeller also recommended, however, that the United States continue to support all foreign governments that happened to be in power (whether we approved of them or not) and that it sell arms and military equipment to them on request, a policy that has only contributed to the volatility of Latin American politics. Such recommendations, together with some of the CIA's activities, have shown clearly that the

United States still places its economic interests in Latin America ahead of the vital interests of the Latin American people.

There is little question that U.S. economic interests will be a source of continuing potential trouble with Latin America, even if aid, trade, and investment reforms are instituted. There is, however, a growing move away from dependency on the United States. More and more Latin American states are trading with each other and with distant parts of the world. Mexico is shipping its newly discovered oil to Brazil, Uruguay, Cuba, Israel, and the Philippines. [16] Brazil is sending its manufactured goods and produce not only to its neighbors, but to China, Japan, the Soviet bloc, and African nations. [17]

The OPEC revolution. Resentment of exploitation by DCs and efforts to adjust the balance began in Latin America, but have spread to other less developed regions as well. Less developed countries are demanding full participation in the industrialization of the world and a full chance to consume their own resources. For example, the Lima Declaration of the U.N. Industrial Development Organization in 1975 set a goal in which 25 percent of the world's industrial production would come from LDCs by 2000, in contrast to 7 or 8 percent in 1975. [18] Nevertheless, given the world's ecology-resource situation, it is questionable whether the wisest course for

---

[17] *New York Times*, January 26, 1975.
[18] Hansen, *A "new international economic order."*

most LDCs now would be to turn away entirely from their roles as commodity-suppliers, even if that were economically possible. It would seem foolish to invest wealth in an attempt to compete with DCs in processing what remains of most industrial resources, escalating environmental destruction in the process.

A much more intelligent strategy for the LDCs would appear to be to strive toward obtaining more stable prices and a much higher return on their commodities, especially their irreplaceable mineral wealth. A start in this direction was made in 1971 when oil-rich nonindustrial countries first banded together in the Organization of Petroleum Exporting Countries to bargain successfully as a group for higher prices for their oil. But the rise of about 20 percent in prices achieved then was virtually nothing compared to the nearly 300 percent (from $3 per barrel to almost $12 per barrel) achieved as a result of the Arab oil embargo between October 1973 and January 1974.

That embargo and the increase in the price of oil shook the industrial world to its foundations and changed forever the relationship between the rich (including OPEC) and the poor nations. It created enormous financial problems for DCs hell-bent on continued economic growth, and it threatened the very existence of some LDCs (as discussed in Chapter 7), *which generally applauded the price increase, nonetheless*. The change in oil prices inevitably will continue to

have profound, far-reaching, and in many cases unexpected consequences for both developed and less developed economies.

The DCs, as has been noted, built their present prosperity on a foundation of cheap energy. Their economies have been geared to run on cheap energy, and old-style economic growth (which is still die stated goal of most politicians and economists) depends on cheap energy. During this century, die industrialized countries have shifted more and more to using petroleum as the source of that energy, despite repeated warnings that the supply of inexpensive, pumpable petroleum was bound to be exhausted shortly after the year 2000. Economists, determined to keep both physical constraints and human behavior out of their calculus, figured in 1961 that only half of the European Common Market's coal production would be profitable in 1970. [19] Planners therefore cut the capacity of the western European and British coal industries virtually in half between 1960 and 1970. Dependence on imported fuels in the Common Market consequently rose from 30 percent to more than 60 percent, and in the United Kingdom from 25 percent to 44 percent.

How could such a shortsighted course of action be taken? Simple. The politicians, economists, and industrialists running the show were confident that the Arabs would never be able to get together with Africans and Latin Americans to jack up the price of petroleum. Oil had always been cheap in the past; therefore, oil would be cheap in the future. Oil would take care of short- and mid-term energy needs. And, if oil supplies really could not be expanded infinitely (or recycled, as one economist has thought possible!), [20] then nuclear power or some other convenient scientific miracle would bail them out in the long term. In their opinion, it would certainly be wrong to maintain a coal industry that had prospects of becoming uneconomic. So the industrial countries now must buy oil from OPEC -- and some of them must buy it regardless of the price.

The United States was in principle in a much better position to tolerate the increase in oil prices than many other nations. In late 1973 the United States was importing about 35 percent of its total petroleum consumption (6 million of the 17 million barrels consumed per day), with a third of those imports coming from Arab states. As a fraction of the *total* energy use in the United States, the imports amounted to around 16 percent. By contrast, Japan and some European countries were dependent on imported oil for 80 to 90 percent of their total energy use. For those countries, a prolonged and effective embargo would have produced complete economic catastrophe; as it was, they were saved by their modest stockpiles of petroleum, by the leakiness of the embargo, and by drastic conservation measures. Clearly, the Arab states did not want to produce catastrophe among their customers; but they did want to exercise

their political muscle and begin to reap the economic rewards to which the world's dependence on their oil entitled them. [21] The extent of that dependence and some hint of its future extent are indicated in Table 15-2.

The immediate effect of the increased oil price on all the industrialized countries was to produce massive trade deficits [22] and to threaten their economies by destabilizing the international monetary system. A veritable flood of money started moving from the DCs to the OPEC nations, primarily to those in the Middle East. In 1974 alone, this flood amounted to some $75 billion more than would have been transferred under the earlier price structure, and it left the nations of the oil cartel with an estimated cash surplus of $65 billion. [23] This does not include increases in

the prices of other energy forms, imported and domestic, that were stimulated at least in part by the oil situation. (The average price of coal delivered to U.S. utilities, for example, rose from around $8 per ton to about $20 per ton in the months immediately following the oil embargo.)

Notwithstanding a great deal of earnest handwringing in the industrial nations about whether the OPEC countries could "productively" absorb so much money so rapidly, they appear to have plenty of ideas on how to spend it. A sizeable amount was promptly reinvested in the industrial economics ("recyling petrodollars"), mainly in stocks of large corporations. (This seemed a clear enough signal that the OPEC countries had little desire to destroy the economies of the industrial world, but the outrage of many staunch supporters of free enterprise at the notion of the Arabs' owning substantial pieces of U.S. business was a bit amusing.) They have also invested heavily in the industrialization of their own countries, and, significantly, they have begun importing much greater amounts of food, primarily from the United States. Some of their funds have been set aside as foreign aid to poor countries.

Two aspects of the flow of petrodollars are less benign. One is that so little of the money is flowing in the direction of the poorest countries -- those that have neither industry nor resources. They were hit extremely hard by the increase in oil prices -- their expenditures on imported energy went up $15 billion, and their expenditures on imported food and fertilizer went up $5.5 billion between 1973 and 1974. [24] The second negative aspect is that so much of the money is being spent on weapons (see "Population, Resources, and War").

But, of course, one country's surplus is another's debt. Added to an already marginal economic situation (for which OPEC was in no way to blame), the financial hemorrhaging, as it has been called, could eventually lead to the bankruptcy of some of the weaker industrial nations, such as Italy. The Organization for Economic Cooperation and Development (OECD) estimated conservatively that by 1980 the members of the oil cartel would have about $300 billion in petrodollars. [25] And the petroleum-importing nations would have accumulated trading deficits equal to that amount. Where might the

[25] Lewis, *Getting even*.

industrial states, burdened by this enormous debt, find the funds to meet their own needs for foreign exchange? And how would they pay the debts themselves?

As the new realities began to sink in, a search for solutions to various energy-related financial problems ensued. Among the early responses were: large increases in expenditures for research and development of alternative energy sources; increased interest in energy conservation and in ways to stockpile oil; and considerable attention to how oil-importing nations might counter the OPEC cartel. Eighteen oil-importing nations formed the International Energy Agency (IEA) in November 1974, with stated objectives of providing security against another oil embargo by means of sharing oil, sharing "equitably among industrial nations the burden of conservation" (whatever that meant), and coordinating measures to stimulate development of alternative sources. [26]

In the United States, the federal government hastily launched Project Independence, which was intended to free the nation from dependence on OPEC oil by the 1980s. In terms of standard thinking about economic growth and the resultant "needs" of the United States, that project was doomed to failure from the start. [27] Serious conservation efforts were discussed but not instituted. In the European Common Market there was talk of cutting reliance on oil imports from 63 percent to 50 percent by 1985 by slowing the growth of energy consumption, rebuilding the coal industry, increasing natural gas production, and accelerating programs to build nuclear power plants. [28]

But, of course, such long-range plans, even if they were effective in reducing oil consumption, could not solve the pressing financial problems of the West. The United States approach to the situation in 1975 fundamentally was to find some way to break the cartel's power and drive prices down again. Such action, at the very least, required unity among the consumers, but that unity proved highly elusive. The basic idea was that, if each nation cut back some on oil imports (one suggestion was for a 3 million bb1/day cutback by all DCs combined, with one-third of the cutback to occur in the United States), then the excess capacity of the OPEC producers (capacity to produce more oil than could be sold at the prevailing price) would become large enough to tempt one of them to break the cartel.

It is even possible that the United States government alone, by interposing itself between buyers and sellers, could break the cartel, as Christopher D. Stone and Jack McNamara of the University of Southern California Law Center have suggested. [28a] The basic idea, in essence, would be to create a new major buyer in the international market -- one interested in lower prices rather than the high prices desired by the multinational oil companies that now control the situation. Furthermore, the use of a bidding system would encourage secrecy, allowing some of the more cash-hungry OPEC nations like Nigeria and Indonesia to cut their prices on the sly. Implementing such a plan, however, would require great political courage, since powerful interests have a huge stake in keeping oil prices high. The billions invested in the Alaskan oil enterprise and Britain's commitment to North Sea oil are just two examples.

The French approach, on the other hand, was that the major consumers, OPEC countries, and the other LDCs should enter trilateral negotiations aimed at reconciling the long-term needs of each group: energy for the West, and capital and aid in industrializing for the OPEC countries and the other LDCs.

Serious difficulties attend all of these approaches. There is no guarantee, for instance, that lowering demand would break the cartel -- and indeed that ploy failed. Far from being hurt by reduced demand, the Arab nations, which have the most abundant supplies, might well prefer to keep their production low in the knowledge that their oil in the ground is going to be even more valuable in the future -- a much more secure nest egg than most of the prospects for investing their petrodollars. They are not fools -- they know that petroleum supplies are not infinite, and they are not hard pressed for cash as are some OPEC countries. Moreover, many DC economies have already been weakened in the 1970s by both inflation and recession -- hardly putting the DCs in a

[28a]How to take on OPEC.

strong position to do economic battle with the oil suppliers. Even though the abrupt rise in oil prices contributed to these economic problems, it is not at all clear that reducing them again would be economically beneficial, especially in the long run.

The French approach to OPEC is more sensible in the long run, and the United States has gradually come around to it, in principle if not entirely in practice. Unhappily, at least through 1976, most effort in the West has gone toward finding ways of temporarily cushioning the blow of the petrodollar drain. The basic palliative has been to find ways to recycle about $60 billion annually in OPEC's surplus oil revenues to consumer nations in financial difficulty so that, in turn, they can buy more oil with it. Several plans have been suggested, all involving direct or indirect borrowing from the OPEC nations. This, of course, would increase the dependence of the consumers on the producers -- but in many ways that seems more attractive than such alternatives as spending dollar and gold reserves (they would be exhausted in a year or so) or gradually selling their countries to the oil cartel.

Meanwhile, the world monetary system has been threatened by a crisis of confidence. Will nations attempt to pay their oil bills by simply printing money, or by restricting imports from OPEC and increasing exports to compensate for the effect of petroleum prices on their trade balances? Nations that managed to do the latter would, in effect, be exporting their deficits to other nations -- opening the prospects of a trade war and worldwide depression. The industrial nations in 1974 pledged themselves against such a course of action, but whether the pledge will hold remains to be seen. Recycling petrodollars could lead to the bankruptcy of many states and the diversion of petrodollar investments into fiscally hardy nations like the United States and West Germany to whatever extent those states are willing to permit foreign investment.

It appears to us that the dilemmas raised by the success of the OPEC cartel (and any successful attempts by LDCs to follow OPEC's example with copper, bauxite, tin, or other commodities)

will only be solved by dramatic changes in attitude, especially in the United States and other DCs, that would permit serious negotiations between rich, oil-rich, and poor countries to take place. The situation can only get worse unless some equitable, long-term plan for allocating the world's resources -- including money -- can be developed.

But arranging rational transfers of wealth would require careful planning, patience, and a degree of international cooperation and good will heretofore unknown. The DCs would have to move consciously to retreat from overdevelopment, most of them foregoing further growth in material consumption (although not necessarily in perceived well-being). The OPEC nations, on the other hand, would have to view at least part of their oil wealth as being held in trust for all LDCs, which they have shown little inclination to do so far. In addition, OPEC would have to show great restraint in dealing with the West for fear of destroying the economies in which they wish to invest their petrodollars and from which they hope to gain assistance in development. One encouraging sign is that the OPEC nations know that oil extraction will not go on forever and that they must look to a time when their nations will be integrated into an international economic system on some basis other than as commodity suppliers.

So far, unfortunately, the developed countries have appeared determined to continue their pursuit of material growth and seem little inclined to participate in any kind of redistribution. As long as DCs agonize over the effect on food prices if the poor should get the money to buy it, or over reduced standards of living in DCs if petrodollars are used by LDCs to absorb goods and services from them, [29] then a rational solution is unlikely to be found. Sad to report, the prospect of military action to break the OPEC cartel was even bandied about [30] and sanctioned as an extreme recourse by Secretary of State Henry A. Kissinger. [31] If this were the path eventually taken by the Western world, then, even if it were "successful," the future would be bleak indeed. For such action would mean that even the barest fundamentals of the global situation, in which all people are increasingly interdependent, have not been grasped by Western leaders. But whatever the outcome of this fast-changing situation, the OPEC revolution has transformed the

power structure of the world dramatically and perhaps permanently.

From the above discussion, it should be clear that a program of raising commodity prices in general, even if successful, would not necessarily help solve the problems of the poor nations -- especially since such price increases would inevitably include the prices of foodstuffs, which many LDCs must import. [32] Poverty is not concentrated where the valuable natural resources are. For instance, Saudi Arabia, which has the world's largest oil reserves (some 175 billion barrels) is inhabited by less than 0.25 percent of the human population. All the OPEC nations together include only 15 percent of the world's population; and nearly half those people live in Indonesia, which is far from being the most richly endowed with oil.

Furthermore, as noted above, the successes of some less developed countries in raising commodity prices may mean disaster for others. As petroleum prices increased in 1974, for instance, India's plight substantially worsened. In the early 1970s India did not consume very much oil (about 200 million bb1/year). But 70 percent of that oil was imported, and 85 percent of it was needed for activities related to development, including irrigation and the production and transport of fertilizer. In 1974 India was forced to spend about 80 percent of its export earnings on oil alone. Whereas in 1970 India's oil imports cost only $140 million, in 1974 they exceeded the $1 billion in foreign aid that had been pledged to India that year by other nations! [33]

Economic problems in the DCs also may have a heavy impact on the poorer LDCs. In 1974 Japan's severe energy shortage resulted in a drop in fertilizer production there, which caused a reduction in Japan's exports to nations like India, Indonesia, and the Philippines, all of which badly needed fertilizer. Similarly, enormous imports of wheat by the Soviet Union in 1972 and 1973 drove prices of that vital commodity up and reduced the supplies that were available to poor countries either through purchase or aid programs. [34]

There is still considerable debate among economists on technical points of tariff and trade policies in general. LDCs have been arguing strongly for measures to raise prices of their commodities, to obtain trade preferences, and generally to increase transfers of resources from DCs to LDCs. [35] Such changes until the mid-1970s were generally opposed by the DCs, and the United Nations Conferences on Trade and Development (UNCTAD) have increasingly seen confrontations along DC-LDC lines since the promulgation of the Prebisch thesis. Most LDCs accept Prebisch's belief that there is a built-in bias in world trade and finance in favor of the DCs, and they have seen in UNCTAD an opportunity to eliminate or even to reverse that bias.

A complicating factor in a system of trade preferences is the power of multinational corporations, which may generate 50 percent or more of the manufactured exports of some LDCs. Some opponents of trade preferences claim that they would largely be a "giveaway" to big business. [36] Once again, the already rich and powerful would benefit, not the poor.

If trade preferences and higher prices on commodities (when imposed suddenly, at least) may cause more problems than they solve, what kind of policies might enable poor nations to improve the lot of all of their people (rather than just a small elite)? The answer seems to lie primarily in changing the goals of development and, as a corollary to that, changing the form in which the necessary aid flows from the rich countries to the poor.

Development Assistance: A Grand Plan Gone Awry

Since 1950 and before, the United States in particular and more recently other developed nations have provided funds in the form of grants or low-cost loans to less developed countries in an effort to help them. Most Americans indeed are far more conscious of the foreignaid budget than they are of the exploitive activities of United States businesses or of the unfairness of U.S. trade policies to LDCs. Surveys even in the mid-1970s

[32] William Schneider, Jr., Agricultural exports as an instrument of diplomacy.

[33]Data on impact of increased oil costs on India are from *New York Times*, December 13, 1973, and January 20, 1974, and from M. F. Franda, India and the energy crunch.

indicated that most people in the United States still supported foreign aid out of generosity, not because it was profitable. [37] Yet, because of the political behavior of Third World nations in recent years (often perceived by uninformed Americans as ingratitude), public support for foreign aid has declined. With that decline, the United States has provided a dwindling share of the total amount of assistance from Western DCs (from well over half to about one-third), and the percentage of the United States GNP thus employed has also decreased (from 0.59 percent in 1963 to 0.29 percent in 1972).

Disillusionment with foreign aid is not limited to the United States; some other donor nations (France, West Germany, and the United Kingdom) have also cut back their assistance, at least as percentages of their GNPs. [38] On the other hand, aid from other countries -- notably the Scandinavian countries, Australia, Canada, China, the Soviet Union, and lately Japan and OPEC countries -has increased since 1960. In 1974 several OPEC countries were far outperforming the West as aid-givers, measured as a percentage of their GNPs. Saudi Arabia, Kuwait, United Arab Emirates, and Iraq gave 3 or 4 percent of their GNPs; tiny Qatar gave a whopping 11 percent. [39]

Total aid commitments from members of the Organization for Economic Cooperation and Development from governmental and private sources reached $25.5 billion in 1975. [40] Of that only $13.5 billion came from governments (more than half of it being loaned, not given, though at low-interest, long-term rates). Much of the remainder ($9.5 billion) had to be spent on goods from the donor country (often at higher cost) or for salaries and repatriation bonuses for Western administrators and technical experts. When all such "catches" were accounted for, the LDCs were left with about $5.3 billion in 1975. [41]

While many LDCs have become somewhat dependent upon foreign aid to keep their economies alive (and in many cases to feed their people), there is a widespread feeling that the United Nations Development Decade of the 1960s and its successor, the Second Development Decade, have failed to accomplish their mission of significantly improving the condition of the LDCs. LDCs also often feel degraded by the strings that have been attached to aid projects and ensnared by seemingly multiplying interest payments. Some recipient countries have at times declined development aid for reasons of politics or pride -- India and Tanzania, among others -although, as a result of economic buffeting by the energy crisis and the world recession, they of necessity have been returning for help.

Traditional Western attitudes toward less developed countries have often seriously complicated DC efforts to help the rest of humanity. Developed countries, both capitalist and communist, have long assumed that they knew what was best for the nations of the Third World. And many

Third World leaders, educated in DCs, have accepted that view. An unspoken assumption of all such aid seems to have been that the best hope for the LDCs lay in emulating the path followed by the DCs, that by applying the ideas of Marx, Malthus, or perhaps Henry Ford, the LDCs could pull themselves out of the mire of poverty.

The hubris of this view has been lost on most citizens of the DCs, but it has become glaringly obvious to many inhabitants of the Third World. The peoples of Indochina developed, among others, the culture that produced Angkor Wat. The Chinese had a venerable civilization when the British still lived in caves and painted themselves blue, and the civilization of India is nearly as old. Africans built Zimbabwe and produced the incomparable Benin bronzes long before Europeans "discovered" them in the nineteenth century. The proud people of Asia, Latin America, and Africa do not appreciate being considered somehow backward and in need of charity.

The original purpose of foreign aid, of course, was to help the underdeveloped world develop in essentially the same ways that Western countries -- and later, the Soviet bloc -- had. This was to be accomplished by concentrating investment in the creation of a modern sector in each developing country -- a core of industrialization in cities, which would provide employment for the growing population and generate a rise in personal incomes and

national GNP. The benefits of that growth were expected to "trickle down" to the poorer strata of society, which were not directly involved in the development effort.

It was an ambitious and, in its purported aims, a rather noble plan, conceived in the expansively optimistic years before 1960. Unfortunately, it did not work. Louis Emmerji, director of the World Employment Programme of the International Labour Organization (ILO) clearly expressed the dismal results of the United Nations Development Decade:

One look at the cities of the Third World today with their inner circles of steel and glass and their outer circles of poverty and junk, tells us that it hasn't worked. The heart of the "modern sector" is an enclave of privilege where a few people receive incomes far above the countries' average whilst the people of the slums and shanty towns lack basic necessities. . . .

The failure of economic growth to "trickle down" led to rising inequalities and the resulting unemployment and poverty. And all the time agriculture languished in low priority -- contributing to the food problem as we know it. [42]

One fatal flaw in the theory was that it overlooked the historical pattern of industrialization in Europe and North America. There, rural development, including small-scale rural industry, preceded urban industry. Indeed, the first inventions and factories fashioned agriculture-related tools and machines. Cities were mainly trading centers; only later was manufacturing located near cities, when nonagricultural consumer goods became the primary output. Even today in DCs, many agricultural items are manufactured in smaller cities in agricultural regions -- an example is the headquarters of Massey-Ferguson, manufacturer of huge tractors and combines, in Des Moines, Iowa. The example for LDCs -- where 50 to 80 percent of the populations are still rural -- should have been obvious. But for urban-oriented economists, planners, and officials, the lesson was somehow overlooked.

The blame for such poor judgement (at least as seen in 20-20 hindsight) cannot all be put on aid donors; much of it lies at the doorstep of decision-makers (government or business) in the LDCs who accepted the assistance and helped to determine the kinds of development that were undertaken. Some of them have been victims of bad advice, however. Perhaps a large share of blame should be pinned on the economists and other development experts who designed aid programs and projects and who promulgated the trickle-down theory. In addition, private investors from DCs -- especially multinational corporations -- have also contributed heavily to the unbalanced pattern of LDC development.

Development and the Environment

One particularly unhappy aspect of some development programs has been their ecological incompetence, a direct consequence of the environmental nearsightedness that has so long afflicted the politicians and technologists of the developed nations. Western technology exported to the LDCs has certainly been a mixed blessing, whether or not that technology has been part of a formal aid program. The consequences of the export of deathcontrol technology to the demographic situation have been examined earlier, as have such problems as were created by the disastrous export of Western pesticide technology to places like the Cañete Valley of Peru. The list, however, runs far beyond this; it includes misuse of pesticides in Malaysia and the encouragement of schistosomal parasites in Africa. In addition, with or without aid and technology from DCs, there has been acceleration of deforestation, soil deterioration, and erosion in Indonesia, India, and Pakistan and in much of Africa and Latin America. In almost every case, great problems could have been avoided or ameliorated if ecologically sound approaches had been taken. [43]

What is perhaps the classic example of misplaced aid in development has been supplied by the Soviet Union. That was the construction of the Aswân High Dam, which may well prove to be the ultimate disaster for Egypt. As has been characteristic of much foreign aid, the ecological consequences and social alternatives were not considered in advance. Irrigation from the dam project, completed in 1970, cannot increase food pro-

---

[42] Workless of the world, *New Internationalist*, October 1975, p. 8.

[43] For examples, see M. T. Farvar and J. P. Milton, eds., *The careless technology*; Jon Tinker, *Is technology neocolonist?*; Erik Eckholm, *Losing ground: Environmental stress and world food*

prospects.

duction enough to feed the number of people that were added to the Egyptian population even during the dam's construction period. This is not a criticism of the dam itself, except insofar as it absorbed resources that might better have been put into population control and agricultural development.

Furthermore, as had been predicted beforehand, the conversion of some 500 miles of Nile floodplain from a one-crop system of irrigation to a four-crop rotation system has had deleterious effects on the health of that population. Perennial irrigation creates ideal conditions for the spread of certain snails which are the intermediate hosts of the blood flukes that cause the serious parasitic disease schistosomiasis (also called bilharzia). Parasitologists expected the Aswân Dam to be the ultimate cause of an explosive outbreak of this disease, and their expectations have been met. The average incidence of schistosomiasis along the Nile between Cairo and Aswân was about 5 percent in 1937. In 1972, following completion of the dam, it had risen to 35 percent, a sevenfold increase. [44]

In addition, the change in the flow of the Nile has had deleterious effects on fisheries in the eastern Mediterranean. It will also have a negative impact on the fertility of the soil of the Nile delta, since the Aswân Dam will restrain nutrients that were previously deposited there annually by the Nile flood. This potential soil depletion will be exacerbated by the growing of several crops rather than one a year. Attempts to solve the problem will undoubtedly include an accelerating use of inorganic fertilizers, with attendant ecological complications.

On the plus side, new fisheries may become established in the Mediterranean and in Lake Nasser (formed behind the dam); it is conceivable that new drugs will help control schistosomiasis, and technology may be able to maintain yields on the newly irrigated land. But, even if most of the problems created by the dam can be solved, two important principles will not have been changed. The first is that all major development projects are bound to have ecological consequences, which should be carefully evaluated at the time of planning, not dealt with haphazardly after the deed is done. The second is that if an effort equal to that involved in the Aswân Dam project had been channeled into population control, rural development, and agricultural production, it could have benefited Egypt far beyond the rewards of even a totally problem-free dam -- especially since in the long run the reservoir behind the dam will silt up and thus become useless.

Bringing land under cultivation through irrigation has long been recognized as no permanent solution to population-food imbalances. Two decades before the completion of the Aswân High Dam, Charles Galton Darwin pointed out that the Sukkur barrage on the Indus River, a dam diverting water to irrigate 2.4 million hectares of India, did not result in adequate diets for people who had previously gone hungry. As he put it, "After a few years the effect was only to have a large number of people on the verge of starvation instead of a small number." [45]

Population can easily increase enough to overstrain any resource, which is precisely what is happening in Egypt today. In the mid-1970s the birth rate in Egypt was estimated to be around

38, the death rate 14, and the growth rate 2.4 percent (doubling time, 29 years). In this context, the Aswân High Dam, which required more than a decade to construct and added to the arable pool of land an equivalent of 800,000 hectares (one-third of the previously cultivated land), is a small project indeed. Egypt would have to complete the equivalent of four more Aswân High Dams before the end of the century just to maintain its present inadequate level of nutrition, if there were no change in yields. Worst of all, the propaganda associated with the dam lulled many Egyptians and others into a false sense of security, so that little was done either to curb the growth of the population of Egypt or to improve its stagnant agricultural system. When the dam was completed, its inadequacy for solving Egypt's food and development problems became evident. Since then, the government has been supporting a national family-planning program and agricultural improvement efforts with considerably more enthusiasm than before.

Roadblocks to development. Disillusionment with development has become widespread, not only because large investments of resources and effort have yielded

[45]*The next million years*, p. 37.

BOX 15-1 The Manpower Explosion in LDCs

One of the unhappy consequences of the rapid increase in the rates of LDC population growth in the 1950s and 1960s is that the children born during that period are now entering the labor pool in large numbers. Some 350,000 more young people are entering the labor force than old people retire each week in south Asia alone. If population growth continues at current rates, the increment will rise to 750,000 per week by the year 2000. This means that about 18 million new jobs are needed per year to provide for these young people and their families. * Needless to say, the cities and budding industries of south Asia cannot begin to meet the need.

These statistics are particularly staggering when considering that unemployment and underemployment have been creating enormous problems throughout these economics for some time already and that competition for jobs was being described as cutthroat before 1970. Furthermore, no successes in birth control, regardless of how spectacular, could affect the statistics for at least the next fifteen years, since the people involved have already been born. The situation in south Asia is more or less characteristic of that in other LDCs, in most of which 20 to 30 percent of the eligible working populations are either unemployed or severely underemployed.

The worker explosion will require dramatic efforts to provide jobs in both urban and rural sectors of LDC economies. Much might be accomplished by concentrating on laborintensive agricultural methods and introducing Social Security-type programs that would permit old or otherwise marginal workers to withdraw from the labor pool without tragic results. Similarly, development in general can produce more jobs if it is carefully planned so that unnecessary mechanization is sharply limited.

If the labor problem is not solved, unemployment and associated disruption may themselves present serious barriers to development. When peasants are forced off the land and can find no jobs elsewhere, they often turn to militant revolutionary groups (such as the Naxalite movement in India in the 1960s and various guerrilla groups in Latin America active in this decade). Land grabs, terrorist activity, and general social disruption have become increasingly common in LDCs in the 1970s, and the link with high rates of unemployment is hardly tenuous.

unexpected and undesired results, but also because various social obstacles have severely impeded progress. Among them, of course, has been the largely unanticipated acceleration of population growth in most LDCs since 1950.

The necessity for population control to permit even limited development of LDCs is plain from practical experience (per-capita income gains being small in the face of record population growth) as well as from economic analysis and computer simulations. [46] Unhappily, population control has proven more difficult to achieve in many LDCs than was originally anticipated for various social and economic reasons (Chapter 13). Moreover, the less developed world today has an unfavorable demographic situation that differs markedly from what prevailed in the DCs during their industrialization. In particular, LDCs are hampered by high dependency ratios (the ratio of economically unproductive to productive people in the population) and explosively growing labor pools (see Box 15-1).

Obstacles to development go far beyond those generated by rapid population growth, however. LDCs would face competition from the DCs if they attempted to compete in international markets by producing manufactured goods. Europe and North America did not have vastly more advanced nations to compete with when they were developing. This is one factor that keeps LDCs in the role of commodity-producers, concentrating on the production of agricultural goods and minerals. The LDCs do, however, have the advantage (or potential advantage) of access to the technological expertise of the DCs. [47]

BOX 15-2 The Soft State

Viewed in the Western cultural context, many LDCs are not unified political units, equivalent in that sense to most DCs. Most LDCs face grave problems of internal equity and social organization, and those problems present formidable barriers in the path of development. Among the most critical difficulties is the prevalence of graft.

Economist Gunnar Myrdal has suggested that the problems of soft states are in part an unfortunate legacy of anarchic attitudes that arose during colonial times. [*] The patterns of civil disobedience, noncooperation, and overt rebellion that developed during the struggles for independence persist and are now operating to the detriment of the indigenous governments. This is not very surprising, especially in countries where elites trained by colonial powers have, on gaining independence, merely continued the operation of the government apparatuses as they inherited them -- and have adopted many of the attitudes of the colonial rulers, as well.

The anarchic patterns flourish along with the corruption that has historically characterized many LDC governments and that is almost invariably a corollary of an illiterate, illinformed, or misled populace. Graft has long been a way of life in most LDCs and is recognized as such by the citizens of those countries themselves. For example, in 1968 Indian Minister for Foreign Affairs and Labor, S. Rajaratnoam, described government by graft as "kleptocracy." He said:

It is amazing how otherwise excellent studies on development problems in Asia and Africa avoid any serious reference to the fact of corruption. It is not that the writers do not know of its existence but its relevance to the question of political stability and rapid economic development appears not to have been fully appreciated. It may also be that a serious probing of the subject has been avoided lest it should offend the sensibilities of Asians. [**]

Most LDCs are traditional societies in which "connections," large-scale graft, and petty bribery (with little loyalty to community or nation) have thrived as an acceptable form of transaction in both business and government. Jon Tinker has vividly described how the system works in the Indonesian family-planning program, where it operates largely to further the program rather than as an obstacle to its implementation:

Family planning staff are not well paid, and as often as not their salaries are mislaid on the lengthy journey from Jakarta via province,

At present, though, there are serious barriers to the transfer of technology inherent in patent laws, license fees, and royalties, and in the tendency of industries to keep their processes and techniques secret. The problems of transferring technology have been accentuated by a lack of scientific and technical traditions in LDC societies or in their educational institutions, most of which were originally established by colonial powers. The consequence is often that, even when a technology might be available, people in LDCs may not appreciate its value or have the necessary background for adapting it to their own use. As Pakistani physicist Abdus Salam described it, "it is not just know-how which the developing countries need; it is also the *know-why*." [48]

At least initially, LDCs also have an advantage in their large pools of cheap labor. This has already been exploited in several countries by multinational corporations, which, for example, have set up factories in Taiwan, South Korea, and Southeast Asia for manufacturing clothing and assembling electronic devices.

Additional obstacles to progress are the burdens of colonial history and traditions, the character of present political decision-making apparatus, the failure of governments to institute land reform, and a wide array of government economic policies. Unfortunately, a narrow focus on economics characterizes discussions about these problems. For instance, economists often point out that the coffee trade has "enriched" Brazil, ignoring the ecological effects of what Georg Borgstrom describes as the "almost predatory exploitations by the coffee plant-

[48] Abdus Salam, Ideals and realities.

regency and district governments to the village clinic. So an illegal charge is made both for a visit to a clinic and for the contraceptive device. . . . Indonesians do not normally accept money to do something they should not do, but instead make a charge for what they ought to do anyway. These payments finance a complex welfare system, both inside each government office and extending outside to the children and grandmothers and cousins of the staff. The corrupt and bloated Indonesian general with his Swiss bank account may genuinely exist for all I know, but he should not be confused with the subtle network of claims and obligations which fans outwards from every Indonesian in a government job. [†]

Such a system can be described as corrupt or irrational only in a context of Western values, of course. Unfortunately, in many areas the system is far less benign.

Although DCs are not wholly free from graft, the populace in those nations generally recognizes graft as an evil, and it is seldom as open and pervasive as in many LDCs. Circumstances compel us to accept this culture-bound Western value judgment. Western medicine and publichealth procedures have been a key factor in promoting overpopulation; Western economic goals are accepted by LDC governments, educational systems, and large segments of LDC populations. As far as we can see, Western-style organizational solutions at this time may be the only kind that offers substantial hope of ameliorating the crises that now face the world society. Therefore, culture-bound as it appears -- and is -- our discussion must be within that framework.

Whatever its origins, corruption undoubtedly increased when partial vacuums were created by the withdrawal of colonial administrations. In general, it has tended to increase since independence and has helped to block many needed social changes, including land and tenancy reforms (for instance, giving tenant farmers a reasonable return on their labors). It often prevents foreign aid from reaching its intended recipients. It greatly weakens local respect for government

and for planning and thus indirectly blocks programs to improve standards of living. It also makes more difficult the kind of coordinated international actions required if efforts like the World Food Program are to achieve maximum success. In short, responsibility for the dismal state of world efforts to help the needy may lie largely at the doorstep of the DCs, but not entirely so.

ers." [49] Dependence on that commodity has not only ruined much of Brazil's soil but is also a major reason why many Brazilians are inadequately fed today.

Furthermore, the LDCs generally lack the cultural traditions that originally led to industrialization in the DCs. As economist Neil Jacoby of the University of California wrote, "development requires a people to choose a new set of philosophical values." [50] The cultural differences show up in various ways. One of them is the pervasive corruption -- especially in government -- that characterizes many LDCs, inducing Gunnar Myrdal to call them "soft states" (see Box 15-2).

DCs have often failed to recognize the strong psychological need of the LDCs for independence. As Deputy Administrator I. G. Patel of the United Nations Development Program put it:

Most of the developing countries have bitter memories of colonial exploitation and racial and other forms of discrimination. Hence, beneath the desire for economic progress is the need to obliterate past hurts and humiliations, to regain dignity and self-respect, which they enjoyed for long centuries but lost during the brief period of Western domination. . . . It is no exaggeration to describe the goals of the developing world today as more psychological than economic, and to perceive that independence is more cherished than economic progress. [51]

The economic and political aspects of development

[51] What the developing countries really want.
[†] Java: Birth control battlefield.

and DC-LDC relationships are extremely complex. [52] But, whatever the "answers" are to the disputed points of policy and questions of who is at fault, it has become abundantly clear that no solution to the general problem can be found until, in effect, the rules of the game are changed.

There is growing agreement that past development policies that focused solely on achieving an industrial takeoff have failed miserably to pull the poorest 25 percent of the world's people out of poverty. As we have mentioned, this is partly because the numbers of the poorest have been increasing much more rapidly than the efforts to help them. [53] Growth in that segment of the population is very rapid and generally is accelerating as death rates fall. But another important reason is that very little has been done directly to help the groups with the lowest incomes in most LDCS.

Recognizing this, both the United States in its bilateral aid program and the World Bank in its multilateral programs have recently shifted their emphases from urban-industrial to rural-agricultural development. In essence, an attempt is to be made to redress the inequities fostered by the previous GNP-is-everything approach, to try to bring the benefits of development to the bottom tiers of two-tiered economies. Efforts are to be made to tackle the problems of the poor directly, instead of depending on "trickle-down" to help them.

As should be apparent by now, the problems of development are a very complex mix of population, food, resource, energy, environmental, social, political, and economic factors. Because of the growing constraints imposed by the various elements of this mix, it is becoming clear that most LDCs cannot and should not be industrialized along DC lines. The most impressive constraints may be the environmental ones. As one biologist put it, "Just think what would happen to the atmosphere if 700 million Chinese started driving big automobiles!"

But it also has become evident that the depletion of high-grade nonrenewable resources would not permit more than a very modest industrial development of most LDCs (unless, of course, there were some sort of massive deindustrialization of most DCs). [53a] Even if the resources of Earth could be mobilized rapidly enough to meet the demands that fully industrializing all LDCs would create, *essential ecological systems would collapse under the added stress*. Whether or not economists and politicians wish to recognize it, growth as occurred in DCs during the past few decades is over, [54] and it will never occur in the majority of LDCs. In an era in which energy costs and capital scarcity are increasing and will clearly continue to do so, only a fool would attempt to push the capital- and energy-intensive United States model of development upon societies already suffering from rampant unemployment.

If large-scale industrialization is not to occur in the LDCs, how, then, are they to develop? Some other course must be found, and we predict it will increasingly resemble the labor-intensive Chinese model. And well it might, for the People's Republic of China is the only large LDC that has made significant strides toward solving its population and food problems and substantially raising standards of living and health for its people. For countries like India and Indonesia, the Chinese model of development offers some hope; the standard United States model (complete with an overmechanized Green Revolution) offers none. The key to successful development also lies partially in the DC-LDC relationship. Without drastic changes in DC attitudes and aid patterns, the LDCs probably will not develop in any sense; rather, many are likely to collapse into chaos.

Aid and International Politics

The problems of foreign aid and development cannot, of course, be divorced from the problems of international politics. Because of their own backgrounds and capabili-

[52] For, example, see Robert O. Keohane and Van Doorn Ooms, *The multinational firm and international regulation*; and Frank and Baird, *Foreign aid*.

[53] John G. Sommer, *U.S. voluntary aid to the Third World: What is its future?*

[53a] Some of the obstacles to extending a DC lifestyle to the world's growing number of poor

people are described in Nathan Keyfitz, World resources. Keyfitz believes that the affluent fraction of the world's population -- those above the poverty level-might be increased from 15 percent in 1975 to 28 percent in 2000 and nearly half by 2025. But even though the population escaping from poverty is projected to increase more rapidly than the total population, or even the population of LDCs, the absolute numbers of the poor would still be greater than today. Keyfitz questions whether resources and technology can be mobilized fast enough to maintain this growth of material affluence without environmental destruction, and we are even more doubtful.

[54]Ehrlich and Ehrlich, *The end of affluence*.

ties, the two most powerful DCs, the United States and USSR, have approached aid differently. The United States, with a vast store of capital to draw on, has seen the problems of the LDCs primarily in terms of a shortage of capital. The Soviets, on the other hand, because of their relatively recent history of revolution and the more recent successful revolutions in two LDCs -- China and Cuba -- tend to emphasize the export not of capital but of political change, of revolution.

Unhappily, many nations threw off the yoke of colonial exploiters after World War II only to have it replaced by home-grown repressive governments. Political scientist Harlan Cleveland put it succinctly: "Nor did freedom for nations lead directly to freedom for individuals. Colonial rule was often supplanted by military rule, Czars were succeeded by commissars, white domination gave way to black dictatorships, extraterritoriality was pushed out by totalitarianism." [55]

The need for dramatic political change in many countries is obvious -- but most recent changes have been in the wrong direction. Haiti (with a per-capita GNP of $70 in 1972) had no chance while it was under dictator François Duvalier, and its present prospects seem no better. The assumption of "emergency powers" by Prime Minister Indira Gandhi of India in 1975, including suppression of dissent, did not encourage optimism for the political future of that troubled country. The autocratic regimes, military or civilian, in many Latin American and African nations, many of them beset by terrorism and revolutionary activity, seem barely able to keep the peace and their seats in power, let alone do much to improve the lives of their peoples. Tales of severe repression and torture of dissidents in Brazil and Chile -- both countries that ostensibly have a great deal going for them -- horrify outsiders and frighten off tourists (if not foreign investors).

Democracy is a fragile form of government, especially where it is not backed by appropriate traditions and some degree of economic equity. Economic equity may be especially important, and a fundamental aspect of equity is landholding. In many nominal democracies, land reform unquestionably is sorely needed to give the people incentive to improve their agricultural practices and a chance to participate in the modernization process. Revolution is one potentially effective way to achieve land reform.

Both the capitalist and revolutionary points of view on aid have a certain validity, but both are also sadly deficient. If real progress in helping LDCs is to be made, both superpowers will have to change their ways. The United States must stop supporting assorted dictators around the world

merely because they claim to be anticommunist. It must accept that in many countries most of the people might well be better off under regimes that the U.S. perceives as communist than under their present regimes. In Latin America, in particular, the need for social justice as a first step toward economic development has been widely recognized (but rarely implemented). If badly needed reforms do not take place peacefully, they will sooner or later be attempted by revolution. It is imperative that U.S. officials in LDCs realize that their contacts within those countries are all too often unrepresentative of the people as a whole. The attitudes of the governing classes in the capitol cities are unlikely to resemble those of peasants or of the masses in urban slums.

There is, of course, no doubt that corporate interests, sensitive to the resource limits of the United States and motivated by the desire for profits, play a substantial role in shaping American foreign policy. The interlocking directorates of the government and various industrial giants are well known. Executives move freely from big business into administrative positions in the government, while high-level bureaucrats and military leaders are welcomed into executive positions with corporations doing business with the government. In 1969, for instance, each of the top twenty defense contractors in the United States employed an average of 65 retired military men of the rank of colonel, navy captain, or higher. [56] The military-industrial complex, among other things, wishes to assure the United States control over the resources it deems essential -- and in the process often has attempted to control the destinies of LDCs.

It is evident that the LDCs can undertake and would profit from having control over their own resources and destinies. The contrary view has often been held in the

[55]Our coming foreign policy crisis, p. 11.

[56]Dennis C. Pirages and Paul R. Ehrlich, *Ark II. Social response to environmental imperatives*.

past as doctrine by the DCs. For example, there were dire (and erroneous) warnings that the Egyptians would be unable to run the Suez Canal when they took it over from the British in 1956. The success of OPEC surely has put that fairy tale to rest once and for all!

Nonetheless, it seems unlikely that there is much to be gained in attempting to shatter the power of international corporations, many of which, among other things, are heavily engaged in the exploitation of LDC resources. A primary reason is that it probably would be impossible in the absence of supporting changes in attitude in DC societies. As long as economic standards reign supreme, economic power will tend to become concentrated; only more fundamental changes will suffice. And those changes must be made with great care. International corporations supply planning, coordination, capital, and expertise in their operations within LDCs; considerable economic hardship could result from a sudden dissolution of those giants. But they could be quickly stopped from draining capital away from the LDCs; after all, the extraction of capital goes against the West's conventional wisdom of what is required to eliminate poverty in those nations.

Russia should face the facts of life, too. The Soviets blame most of the problems of the world on capitalist imperialism, but that just is not supported by the evidence. Revolution is at best a partial answer; it cannot remove the biological and physical constraints upon development, although it may well remove some of the social and economic barriers. At worst, as noted above, revolution only replaces one despotism with another. Furthermore, the Soviet Union's intervention in other countries in defense of what it perceives as its vital interests has been fully as blatant and brutal as that of the capitalist imperialists, as the Soviet invasion of Czechoslovakia in 1968 so clearly demonstrated. It is ironic that the USSR, in Angola and elsewhere, now seems to be emulating the grand imperialism pioneered in the nineteenth century by western European powers and the United States.

But the differing approaches of the United States (as well as other Western nations) and the USSR, which dominated international politics in the first two decades after World War II, must now share the stage with the policies of the LDCs themselves, which are increasingly determined to narrow the gap between the rich and the poor. The OPEC revolution has shown that traditional international politicoeconomic relationships can be dramatically and profoundly altered. And even if, as some claim, the case of oil is unique, the self-interest of the rich nations is clearly tied to the condition of the poor. As Harlan Cleveland has written, "If two-thirds of the world simply failed to cooperate in international arrangements that require general consent -- nuclear safeguards, weather watch, crop forecasting, public health, narcotics control, environmental monitoring, and measures against hijacking and terrorism -- everybody would lose, but the world powers would likely lose the most." [57]

In short, for the world commons to operate for the benefit of all people requires it to be administered cooperatively -- and the poor can demand a price for their cooperation. More positively, there is general agreement among the rich that poverty *should* be wiped out -- and that consensus would make selfishness a more difficult course (although one that certainly might yet be taken).

International politics in the near future will most likely be focused on the question of whether the rich and the poor can strike a new *planetary bargain*, to use Harlan Cleveland's term. Can the developed countries show the necessary self-restraint and the less developed countries the necessary changes in attitudes and organization to rearrange the relationships among nations successfully? There are some hopeful signs.

A group consisting of most Third World nations, calling themselves the Group of 77, in 1974 presented a case to the United Nations for a New International Order. In May 1974 the United Nations General Assembly adopted by consensus a Declaration on the Establishment of a New Economic Order, whose stated alms include: "to correct inequalities and redress existing injustices and ensure steadily accelerating economic development, peace and justice for present and future generations." [58]

The Declaration called for stabilization of commodity prices and markets for them and for establishment of a link between those prices and prices paid for manufactured products imported from DCs. It also called for

[57]Our coming foreign policy crisis, p. 13.
[58]The new economic order, *New Internationalist*, October 1975 (a special issue on this subject).

restraint of research into synthetic substitutes for commodities, which have already damaged markets for some products, such as sisal, jute, and rubber. (Higher prices and diminishing resources of petroleum will eventually undermine this activity, but that is little comfort to LDCs today.) Finally, the New Economic Order would encourage the development of producer associations and trade unions among LDCs in order to negotiate favorable trade terms more effectively. Such trade associations, while not having the clout of OPEC (where conditions were uniquely suitable for setting up a cartel), have already been established for several commodities, including bananas, cocoa, coffee, copper, phosphates, tea, and tin. [59]

The reaction to the New Economic Order among DCs, especially at first, was generally negative, and the United States was the most recalcitrant. But it soon became obvious that the demands of the Group of 77 could not be ignored. United Nations Secretary General Kurt Waldheim told a later United Nations conference in Lima, Peru: "the New Economic Order is the price of peace." [60]

In September 1975, in an address before the United Nations by Secretary of State Henry Kissinger, the United States officially took a stand favoring new bargains, including a "fundamental structural improvement in the relationship of the developing countries to the world trading system . . . such as preferences, favorable concessions, and exceptions which reflect their economic status." [61] Kissinger also urged the world community to address the basic problems of access of LDCs to capital markets, the transfer of technology, and "the principles to guide the beneficial operation of transnational enterprises." He pointed out the need for controlling population growth, for increasing food reserves, and for reducing food wastage, and he pledged the United States to contribute to a program of action if all nations "met in a spirit of common endeavor." The speech ended with some interesting rhetoric:

My government does not offer these propositions as an act of charity, nor should they be received as if due. We know that the world economy nourishes us all, we know that we live on a shrinking planet. Materially as well as morally, our destinies are intertwined. . . .

There remain enormous things for us to do. We can say once more to the new nations: We have heard your voices. We embrace your hopes. We will join your efforts. We commit ourselves to our common success.

Although the speech did not indicate awareness of many of the concerns of this chapter, it did indicate a growing power within the United States government of persons who realize the degree to which all nations are interdependent and understand that the future of the United States depends on how well the entire world deals with the population-resource-environment crisis. No doubt the success of the OPEC cartel's embargo and raising of oil prices also had much to do with the United States change of heart toward the aspirations of poor countries. History makes it

difficult to believe that the change in attitude could have been accomplished without the bludgeon of OPEC oil or some similar weapon in the control of the nonindustrial nations.

How much action will follow the rhetoric remains to be seen. And how ready the LDCs are to put aside their own rhetoric and join in common solutions to common problems also is in doubt. Unfortunately, less than three months after the Kissinger speech, the use of the United Nations as a forum for divisive propaganda on the part of the Eastern and Third World blocks reached an extreme with the unfortunate "Zionism is racism" [62] declaration. That declaration strengthened, at a critical time, isolationist forces in the United States who already considered both the United Nations and foreign aid utterly useless. The declaration was followed a few months later by a failure of Third World and communist nations to join the Western nations in a worldwide condemnation of international terrorism or to agree to oppose it and refuse cooperation with extortionists.

There is a real danger that the past colossal failures of both the United Nations and foreign-assistance efforts will lead to a withdrawal of the United States from efforts to help solve vital international problems. It would behoove all governments to remember that, with-

out the wholehearted collaboration of the United States, western Europe, the USSR, and the People's Republic of China, any resolution of world problems is extremely unlikely. And failure to resolve them will most likely lead to war.

POPULATION, RESOURCES, AND WAR

Desmond Morris some years ago observed, ". . . the best solution for ensuring world peace is the widespread promotion of contraception and abortion . . . moralizing factions that oppose it must face the fact that they are engaged in dangerous war mongering." [63] As he suggested, population-related problems may be increasing the probability of a thermonuclear Armageddon. Avoiding such a denouement for civilization is the most pressing political-economic problem of our time.

In 1969 the world saw in a microcosm what may be in store: Two grossly overpopulated Central American countries, El Salvador and Honduras, went to war against each other. El Salvador had an estimated population of 3.3 million, a population density of 160 people per square kilometer, with a doubling time of 21 years. Honduras had a population of 2.5 million, a density of only 22 per square kilometer, and the same doubling time as El Salvador. More significant statistics have been provided by the Latin American Demographic Center; they show that in El Salvador the

population density per square kilometer of arable land was 300 persons, while in Honduras it was only 60 persons.

Almost 300,000 Salvadorans had moved into Honduras in search of land and jobs because of overpopulation and resulting unemployment at home. Friction developed among the immigrants and the Honduran natives; El Salvador accused Honduras of maltreating the Salvadorans; and the problem escalated into a brief but nasty war. The conflict was ended by the intervention of the Organization of American States (OAS). In a precedent-shattering move, the OAS recognized demographic factors in its formula for settling the dispute -- an international body acknowledged that population pressure was a root cause of a war. [64]

Systematic analyses of the role of population pressures in generating wars, carried out by political scientist Robert C. North and his colleagues at Stanford University, have supported earlier conclusions based on anecdotal evidence. Statistical studies of the involvement of major European powers in wars in modern times have revealed very high correlations among rates of population growth, rising GNP, expanding military budgets, and involvement in wars, although technical considerations make drawing conclusions about causes and effects hazardous. In more detailed multivariate analyses, Professor North found a complex causal chain involving population growth in relation to static or slowly growing resources, technological development, a tendency to invest energy beyond previous boundaries of society, and increases in the presumed needs and demands of a populace.

Writing about the root causes of World War I, North and political scientist Nazli Choucri of the Massachusetts Institute of Technology concluded:

Our most important finding is that domestic growth (as measured by population density and national income per capita) is generally a strong determinant of national expansion. Our investigations have identified strong linkages from domestic growth and national expansion to military expenditures, to alliances, and to international interactions with a relatively high potential for violence. [65]

In ancient times such tendencies were somewhat buffered by oceans, mountain ranges, deserts, vast distances, and slow means of travel. Rome could raze Carthage but not China or the cities of South American and Central American Indians. Today, however, with vast increases of population and unprecedented developments in technology, transportation, and communications, the peoples of the world are cheek by jowl, and there is little geographical buffering left. North pointed out that states in nonaggressive phases, like modern Sweden, tend to share certain characteristics: "A relatively small and stable population, a relatively high and steadily developing technology, and good access to

[63] *The naked ape*, McGraw-Hill, New York, 1967.
[64] *Population Bulletin*, December 1969, pp. 134-135.
[65] *Nations in conflict: National growth and international violence*.

resources (either domestic or acquired through favorable trade)." [66]

Finite resources in a world of expanding populations and increasing per-capita demands create a situation ripe for international violence. The perceived need to control resources has been a major factor in U.S. military and paramilitary involvements around the globe since World War II.

The role of resources in motivating United States intervention in Southeast Asia, for example, has been stated explicitly by many American political leaders. Richard M. Nixon said in 1953, when he was vice president: "If Indo- China falls, Thailand is put in an almost impossible situation. The same is true of Malaya with its rubber and tin." President Dwight D. Eisenhower wrote in 1963: "The loss of all Vietnam together with Laos in the west and Cambodia on the southwest . . . would have spelled the loss of valuable deposits of tin and prodigious supplies of rubber and rice." In a magazine interview in 1954, President Eisenhower also mentioned tungsten as being an important resource found in Indochina. [67] The same magazine was headlined, "Why U.S. Risks War in Indo-China." A paragraph below the title of the article was: "One of the world's richest areas is open to the winner in Indo-China. That's behind the growing U.S. concern. Communists are fighting for the wealth of the Indies. Tin, rubber, rice, key strategic raw materials are what the war is really about. U.S. sees it as a place to hold--at any cost." A listing in the article of the components of "the big prize: Southeast Asia" included tin, rice, rubber, oil, minerals (tungsten, iron, zinc, manganese, coal, and antimony), and foodstuffs.

The view of United States politicians was not changed by active entry of the nation into the Vietnam war in the mid-1960s, despite a great deal of propaganda about saving the people from communist control. President Lyndon B. Johnson in 1966 bluntly told soldiers at Camp Stanley in Korea: "They want what we've got and we're not going to give it to them." Greatly increased oil exploration in Southeast Asia and the mapping-out of oil leases in the waters off South Vietnam in 1970 added credibility to the importance of resources as a factor in the United States involvement. Ironically, once the war was "lost" in 1975, American oil companies resumed their exploration activities with permission of the new regime, unhindered by dangerous military activity.

The United States thus has shown itself to be willing to fight under some circumstances to protect its resource base and to deny resources to others. It also has been willing to attempt intervention in the internal affairs of LDCs to assure that governments friendly to United States investors and sympathetic to our resource needs remained in power, as CIA activities before the Allende coup in Chile and earlier against Castro in Cuba demonstrated.

This approach clearly is still a factor in United States foreign policy, and it will continue to be if the business community has its way, although business has become somewhat more sophisticated in its perceptions of resource realities. For example, in 1971 before the Vietnam war was over, an article in *Forbes* magazine complained about the growing U.S. dependence on foreign sources for raw materials: "Unfortunately, all this is happening at a time when the Vietnam war and the world balance of power make it almost impossible for the U.S. to defend its overseas supply sources. When we practiced gunboat diplomacy, we really didn't need it. Now, when we need it, we can't use it." [68]

In late 1974, when American troops were no longer fighting in Vietnam, the Arab oil embargo aroused new talk of gunboat diplomacy. Although the embargo lasted only a few months, the subject continued to be debated in the press and academic literature, while the U.S. army carried out desert maneuvers. [69] There was even a reflexive urge in the U.S. government to join the fighting in Angola against the USSR in 1975, even though U.S. resource interests in that poverty-stricken country were trivial at most. Indeed, the reasons for Soviet intervention there remain something of a mystery, given the previous lack of success of the Soviets in establishing a lasting sphere of political influence in Africa.

If the rich countries insist on continued expansion of their cowboy economies, accelerating competition over

the dwindling resources of the planet can be expected. Moreover, if nations fail to establish rational control of the oceans, squabbles over rights to shrinking fishery yields or to seabed resources may also precipitate serious conflicts. Since, even if nations should move in the right direction, competition for resources is almost bound to become increasingly intense for some time, it is crucial that legal devices quickly be developed for the resolution of such international conflicts.

International Conflict in the Nuclear Age

Indeed, it is in the area of international conflict above all that the old rules must be changed. [69a] Most national leaders still view war as "continuation of politics by other means," as Clausewitz described it in the early nineteenth century. Politicians still seem not to have learned that thermonuclear war *itself* is a far more deadly enemy than any other nation. They still talk of winning, when in reality only losing is possible. In the United States in 1975, there actually was some consideration of "first use" of nuclear weapons. Secretary of Defense James R. Schlesinger stated, "The first use of . . . nuclear force, even in very limited ways, carries grave risks of escalation *and should be considered only when the consequences of conventional defeat would be even more serious*" (our emphasis). [70] We find it difficult to imagine a situation in which "the consequences of conventional defeat" could be worse than those of a nuclear exchange, especially since confinement to a "very limited" force seems highly unlikely.

The conclusion seems inevitable that if nations continue to build and distribute nuclear arms and biological weapons, sooner or later World War III will occur. And it *will* be the war that ends all wars -- at least all world wars -- for a very long time, if not forever.

Unfortunately, a great deal of United States policy with regard to national defense is founded on the idea of *a balance of terror*, a concept created by a group of scientists specializing in what is known as the *theory of nuclear deterrence*. What the politicians apparently do not know (or refuse to believe) is that this theory is based on assumptions that have been demonstrated to be untenable, analyses that are inapplicable, and nonexistent or irrelevant data. [71] A similar foundation has been developed in parallel by the Soviet Union for its military policy.

Why would presumably intelligent people be taken in by transparent theorizing? Because the "analysis" of the military situation can be conveniently arranged to produce desired results; the answers are engineered to fit precisely the expectations of the appropriate government officials. Leaders of nations naturally believe that their nations must be strong if they are to survive. Nuclear weapons fit right into a pattern that has prevailed throughout human history, one that dictates arming against an enemy in order to avoid attack. In the past, the stronger society in a conflict always won. But nations have not been able to adjust to the new rules of the game: *with thermonuclear weapons, regardless of which side is stronger and which attacks, both sides will lose*. A National Academy of Sciences report released in 1975 painted such a grim picture of the probable consequences of a nuclear war that Philip Handler, president of the academy, said he could only be "encouraged" by its conclusion that some people would survive somewhere. [72]

Four elements make recognition of the new rules and acting upon them difficult. First, there are always scientists who will tell politicians that nuclear or chemicalbiological wars can be won. If the other side is utterly destroyed and 20 million Americans survive the conflict, is that not victory? Even if the U.S. had just two survivors and the other side had none, that would spell victory to some politicians. The late Senator Richard Russell, for example, said in 1969, "If we have to start over again with another Adam and Eve, I want them to be Americans."

[69a] A crucial source on the analysis of international relations is Robert Jervis , *Perception and misperception in international politics*.

[70] From Report to Congress on nuclear force posture in Europe under P. L. 93-365, May, 1975. See also Frank Barnaby, *Changing nuclear myths*.

[71] Details may be found in Philip Green's *Deadly logic*. See also the Stockholm International Peace Research Institute paper, *Why arms control fails*; The myth of deterrence lulls world opinion.

[72] See, for example, Bernard T. Feld, "The consequences of nuclear war"; National Academy of Sciences (NAS), *Long-term worldwide effects of multiple nuclear weapons detonations*. The report, by the way, neglected many of the worst ecological and social consequences of a nuclear conflict. See the amusing comment of "Adriadne" on the NAS report in *New Scientist*, October 23, 1975; and the "Federation of American Scientists" press release, *The National Academy of Sciences* seems to lack public policy sense, October 4, 1975.

Deterrence and the balance of terror. A second element is the notion that stockpiled weapons will not be used, that the balance of terror will be a stable one. This notion has been examined in detail by behavioral scientists, and few of them seem anxious to bet on it.

Most Americans, however, seem to feel that the chances of thermonuclear war are remote. Many, for instance, apparently believe that the limited test-ban treaty negotiated during the 1960s greatly diminished the chances of thermonuclear war. Their confidence stands in sharp contrast to the apprehension of those most concerned with the arms race. In 1964, for instance, a survey of experts at Rand Corporation (a militaryindustrial think tank) revealed the following subjective estimates of the probability of thermonuclear war: 1 chance in 10 in 10 years, I chance in 4 in 25 years.

Other knowledgeable people do not seem to consider World War III any less likely to occur. Professor Bernard T. Feld, former Director-General of the Pugwash Conferences on Science and World Affairs, wrote late in 1974:

The world is entering upon perilous times -- perhaps the most dangerous period in its entire history. It is my judgement that the odds are around one in three that a nuclear weapon will be used in a conflict situation before the year 1984; and that the chances are greater than fifty-fifty for nuclear war to occur in the 26 years remaining in this century. [73]

Disagreements among arms-race experts culminated in the anti-ballistic missile (ABM) controversy of the early 1970s. Well-informed people realized that the deployment of multiple independently targeted reentry vehicles (MIRVs) and ABMs promised to destabilize the balance of terror. A missile equipped with a MIRV can strike at a series of targets. The payload is a vehicle known as a bus, which drops off a series of warheads aimed independently at different targets. An ABM is a system for destroying incoming enemy missiles.

The combination would greatly increase the advantages of making a first (preemptive) strike. Each missile with a MIRV is a single target in its silo, but it would become a salvo once launched. A preemptive counterforce strike against an enemy's missiles might, with the multiplicative advantage of MIRVs, saturate the enemy ABM capability and destroy much of the opponent's strike capability. The aggressor could launch a preemptive strike and then hope to use its ABMs to shoot down most or all of its enemy's weakened second strike. The aggressor could thus hope to escape with little or no damage. (The ecological and radiation dangers to the entire planet rarely are considered major factors in military-governmental war scenarios.) The principle of *mutually assured destruction* (appropriately labeled MAD) upon which peace is supposed to be based will have been violated. [74]

Although strict limitations were placed on the deployment of ABM systems in the United States and the Soviet Union (see Box 15-3 for a chronology and description of international arms-control agreements since World War II), both nations are now engaged in a race to improve the accuracy of their MIRVed missiles and to move on to MARVs (maneuvering reentry vehicles), which are even more difficult to intercept and which are equipped with multiple warheads that can be sent Earthward in different directions and at different speeds. United States ICBMs could hit within 350 meters of a target at a range of more than 10,000 kilometers in 1975. In the near future, accuracy should improve three- to tenfold. [75]

Further improvement in accuracy is also possible through the use of self-guided cruise missiles. Cruise missiles are essentially pilotless jet airplanes carrying warheads. Recent technological

developments permit such missiles to be fitted with computers for terrainmatching and recognition, which allows them to determine their positions in flight with an accuracy of within 7 to 10 meters anywhere on Earth -- thus allowing virtual pinpoint delivery of nuclear warheads. [76]

The Strategic Arms Limitation Talk (SALT) negotiations between Secretary General Leonid Brezhnev and President Gerald R. Ford in Vladivostok in autumn 1974 appear to have set a limit of 2400 delivery vehicles for nuclear weapons for each nation. That number, with

[74] A helpful guide to the jargon of nuclear war is the United States Arms Control and Disarmament Agency's *SALT lexicon*.

[75] Barnaby, "Changing nuclear myths". Technically, accuracy is described in terms of a circular error probability (CEP). With a CEP of 100 meters, at least one-half the missiles launched will land 100 meters or less from the target.

[76] Kosta Tsipis, "The long range cruise missile".

BOX 15-3 Arms Control Agreements

Since World War II, the nations of the world have made sporadic attempts to reduce the threat of Armageddon by entering into agreements on the use of the ever-more-potent weapons developed by their scientists. To say that those agreements are inadequate would be an extreme understatement. Aside from biological weapons, they have not led to the destruction of a single arm, not even a pistol, let alone an ICBM. The arms agreements do, however, represent some stumbling steps, often in the right direction, and they are symbolic of the healthy respect that society in general has for the new weapons.

There have been several multilateral agreements:

1959, *Antarctic Treaty*. Prohibits all military activity in the Antarctic area and makes the area the first zone to be kept free of nuclear bombs. In force by 1961, it had seventeen signatories by the end of 1973. Disarmament advocate Philip Noel Baker said of this treaty, "While disarming Antarctica we put 7000 nuclear weapons in Europe. We should have disarmed Europe and put those weapons in Antarctica."

1963, *Partial Test-Ban Treaty*. Prohibits detonation of nuclear bombs in the atmosphere, under water, and in outer space but not underground. In force by 1963, this had 106 signatories by 1973. The Stockholm International Peace Research Institute (SIPRI) regarded it mainly as an

antipollution measure: "The first modern international treaty to control the contamination of our environment."

1967, *Outer-Space Treaty*. Prohibits all military activity in outer space, including launching of nuclear weapons into Earth orbit. In force by 1967, the treaty had seventy-one signatories by 1973.

1967, *Treat of Ttatelolco*. Makes Latin America a second zone free of nuclear weapons. In force in 1967, the treaty had eighteen signatories by 1973. Unfortunately, Brazil and Argentina, the two outstanding candidates for the nuclear club in the area, have not fully accepted the treaty. Without them it is worthless.

1968, *Nuclear Nonproliferation Treaty (NPT)*. Prohibits the obtaining of nuclear weapons by nations not already possessing them. Signatories with nuclear weapons promise not to give them to others or assist others in making them. In force in 1970, the treaty had ninety-seven signatories by 1976. France, India, Israel, and China, among the nuclear powers, have never signed, nor have South Africa and Argentina, either of which could quickly build bombs. Pakistan, Brazil, and Spain are among other nonsignatories with the capacity of building bombs within perhaps five years, and signatories Canada, Iran, South Korea, and West Germany could quickly join the nuclear club if they wished to withdraw from the NPT. Article 6 of the NPT pledged the nuclear powers to "pursue negotiations in good faith on effective measures relating to cessation of the nuclear arms race at an early date and to nuclear disarmament." The failure of some signatories to keep that pledge could be used as an excuse for others to renounce the treaty.

1971, *Seabed Treaty*. Prohibited weapons of mass destruction on the ocean floor. It was put in force in 1972 and had fifty-seven signatories by the end of 1973.

highly accurate MIRVing (or MARVing) and/or the use of cruise missiles, would permit the deployment by the Soviet Union and by the United States individually of *2 to 3 times* the number of warheads believed necessary for a successful counterforce strike against the other nation's ICBMS. [77]

Thus, even without extensive ABM deployment, the temptation to make a first strike on the enemy's nuclear forces might be too much for military minds to forego in a time of extreme tension. There is no certainty that the remaining undamaged missiles would be launched at the aggressor's cities, since this would invite retaliation in kind. But either the United States or the USSR would have more than ample warheads to destroy the other nation completely *after having either launched or received* a successful counterforce strike. In 1974, for instance, the United States at well below the Vladivostok limits could deliver some 8000 nuclear warheads; both the United

[77] L. J. Carter, *Strategic arms limitation*; pt. 2, "Leveling up" to symmetry.

1972, *Biological Weapons Convention*. Prohibited the development, production, and stockpiling of bacteriological and toxin weapons and requires destruction of existing stocks. It was not in force by 1974, but there were thirty-one signatories in 1973.

In addition to the multilateral agreements, eight bilateral agreements have been made between the United States and the Soviet Union, each of which went into force the year it was signed. And three SALT II agreements had been reached in 1974 that had not yet been ratified by Congress in early 1975.

The bilateral agreements are:

1963, *"Hot-Line" Agreement*. Established direct telephone and telegraph connection between the two governments for use in emergencies. (The facilities have been used.)

1971, *"Hot-Line" Modernization Agreement*. Added two satellite communications circuits to the system to increase its reliability.

1971, *Nuclear Accidents Agreement*. Specified procedures to reduce risk of accidental war by notification and exchange of information in case of accidental or unauthorized explosion of a nuclear bomb.

1972, *High Seas Agreement*. Designed to prevent dangerous incidents involving ships or aircraft on or over the oceans.

1972, *SALT I ABM Treaty*. Limited deployment of ABMs to a maximum of 100 missiles and launchers at each of two specified sites in each country.

1972, *SALT I Interim Offensive Arms Agreement*. Provided a five-year freeze on the aggregate number of ICBMs and SLBMs (submarine-launched ballistic missiles), on each side, but did not restrict the numbers of strategic bombers.

1973, *Protocol to High Seas Agreement*. Prohibited simulated attacks by each country on nonmilitary ships of the other.

1973, *Nuclear-War-Prevention Agreement*. Provided for consultations when it appears there is a risk of war between the two nations and moved a short distance in direction of a "no-first-use" agreement.

1974, *SALT II ABM Treaty*. Reduced deployment of ABMs to one site in each country (USSR chose Moscow, and the United States, a Minuteman ICBM site; both ABM systems are questionably effective).

1974, *SALT II Threshold Nuclear-Test-Ban Treaty*. Outlawed underground tests of nuclear bombs with yields in excess of 150 kilotons. This was intended to be in force in 1976.

1974, *SALT II Interim Offensive Arms Agreement*. Committed United States and USSR to negotiate extention of the SALT I Interim Offensive Arms Agreement through 1985.

1974, *Vladivostok Accord*. Agreement reached by President Gerald Ford and Leonid Brezhnev that for the next ten years each nation would be limited to 2400 strategic missile launchers, of which no more than 1320 would be armed with MIRVed missiles.

Sources: Alva Myrdal, "The international control of disarmament", 1974; Bernard T. Feld, "Doves of the world unite!"; International Atomic Energy Agency, *A short history of nonproliferation*; Stockholm International Peace Research Institute (SIPRI), "Why arms control fails". See also Ramsdell Gurney , "Arms and the men"; Paul H. Nitze, "Assuring strategic stability"; *Time*, April 11, 1977.

States and the USSR are considered to have *fewer than 100 cities that would make worthwhile targets*. [78] Fewer than 2 percent of the warheads therefore would have to survive the first strike. We must also note in passing that even a strictly counterforce strike aimed only at missile sites would kill many millions of people outright, enormously increase the human load of cancers and mutations, and produce untold ecological consequences.

Hence there has developed a trend away from the basic idea of deterrence: MAD, the possession of invulnerable nuclear weapons by both sides so that attack and retaliation would perforce be aimed against population centers (and therefore presumably be unthinkable). [79] In place of such deterrence, the situation could be one in which a nation receiving a counterforce strike must

[78]Frank Barnaby, "The Ford-Brezhnev agreement assessed".

[79]There has been discussion of moving back toward this posture with a land-based mobile ICBM system (Kim Willanston and Lloyd H. Norman , "Missiles on the move", *Newsweek*, February 16, 1976.

choose to retaliate against its opponent's cities in the sure knowledge that it is committing suicide in so doing. The significance of this change is difficult to judge. The United States has officially added a counterforce option to its deterrence strategy, a step that may simply be an attempt to make limited nuclear wars thinkable -- part of the "if you've got the hardware, you ought to use it" philosophy that so often seems to characterize military "thinking."

Whether or not these new trends weaken the balance of terror may, however, be beside the point, for deterrence theory itself is fundamentally flawed. The underlying assumption of deterrence theory -- that leaders will behave rationally -- is not only weak, but has been repeatedly contradicted by history. Scientists may make guesses about the probability of a thermonuclear war, but their guesses are really no better than the guesses of any informed person. [80] We agree with those who feel that the nuclear arms race, ostensibly intended to deter aggression and increase national safety, has in actuality greatly *reduced* the security of the United States.

Nuclear proliferation. The larger the number of nations that possess nuclear weapons, the greater the likelihood of nuclear war would seem to be. This conclusion seems obvious enough: countries that do not have nuclear bombs cannot use them in whatever conflicts they are involved in; for a given number of conflicts, the bigger the fraction in which one or more parties have nuclear arms, the bigger the chance that such weapons will be used. The counterargument has been advanced that, in a world where many countries have nuclear weapons, everyone will be more careful and there will be fewer conflicts altogether, but we and many others find this view unconvincing.

The spread of nuclear weapons to more nations is called proliferation. (Among specialists the term hori*zontal proliferation* is often used; *vertical proliferation* means an increase in number or sophistication of weapons within a nation.) Countries known to have exploded nuclear weapons prior to 1974 were the United States, the Soviet Union, France, the United Kingdom, and the People's Republic of China. In 1974 India became the sixth member of the "nuclear club" by exploding a nuclear device underground in the Rajasthan desert. India claimed this device was a "peaceful nuclear explosive" (abbreviated PNE in most arms-control discussions), but in fact there is no practical difference between such a device and a weapon.

The Nonproliferation Treaty (NPT), which went into force in March 1970 upon ratification by forty-three signatory nations, was intended to prevent the spread of nuclear weapons beyond the five nations that had them then. [81] Obviously, it did not stop India, nor has it stopped Israel, which has not yet exploded a nuclear weapon but is acknowledged in the intelligence community to possess them. [82]

The biggest weakness of the NPT is that not everyone subscribes to it. More than a third of the nations of the world were not party to the treaty as of December 1975: forty-two nations, including India and Israel, had not signed; another fourteen had signed but not ratified it; and ninety-seven nations were parties to the treaty. Among the holdouts were nuclear-weapon states France and China, together with a number of countries having the capability and perhaps some incentive to acquire nuclear weapons: Pakistan, Brazil, Argentina, Chile, Egypt, Indonesia, South Africa, and Spain, for example. [83]

The NPT's stipulations are in any case not particularly strict. Party states that have nuclear weapons agree not to transfer these to any states that do not have nuclear weapons or to assist or encourage such states to acquire nuclear weapons. Party states that do not have nuclear weapons agree not to acquire them, either for military or peaceful purposes. The parties without nuclear weapons also agree to a set of safeguards applied by the Interna-

---

[80] A good introduction to this problem is to read the three books by Herman Kahn listed in the bibliography of this chapter, followed by Green's *Deadly logic*, Jerome D. Frank's *Sanity and survival*, and Herbert F. York 's *Race to oblivion* and Arms control, Plate's *Understanding doomsday*, and finally Robert F. Kennedy's *Thirteen days*, Norton, New York, 1969. These will provide the reader with some background for making his or her own predictions.

[81] Good background on the NPT, including the full text of the treaty and a synopsis of the NPT Review Conference of 1975, is available in International Atomic Energy Agency, *A short*

history of proliferation.

[82]See, for example, CIA estimates that "Israel has 10 to 20 nuclear weapons available for use," *New York Times*, March 15, 1976, p. 1.

[83]See William Epstein, "the proliferation of nuclear weapons"; and Norman Gall, "Atoms for Brazil, dangers for all".

tional Atomic Energy Agency to ensure compliance with the treaty. The safeguards all have to do with accounting for the whereabouts of special nuclear material used and produced in the peaceful nuclear energy programs of these countries. (Special nuclear material refers to that which is suitable, without further isotopic separation, for making nuclear explosives.) Even if the safeguards work perfectly, however, they can only *detect* the diversion of special nuclear material for explosive purposes; they cannot prevent it. It is possible that a country determined to evade even detection could do so, and the only sure penalty for detection would be some measure of international outrage -- a price many a nation has paid before in its perceived self-interest. Any party to the NPT can withdraw from it openly with three months' notice to the United Nations Security Council.

The NPT has been further weakened by the behavior of the weapons states that signed it. Their obligations under the treaty include pursuing negotiations in good faith toward cessation of the nuclear arms race and toward complete disarmament; the nonweapons states believe -- rightly in our view -- that these obligations have not been met. The NPT also calls for mutual assistance in securing the benefits of peaceful nuclear technology for all parties to the treaty. But the United States has been freer in its transfers of nuclear technology to certain DC nonparties to the treaty (for example, Spain and South Africa) than to LDCs that are parties to the treaty. This has made the LDCs wonder aloud just what benefits they are receiving by adhering to the NPT.

The principal real barriers to proliferation have been good intentions (as exemplified by but not restricted to the NPT) and lack of easy access to the special nuclear materials needed to make nuclear weapons. Lack of knowledge of how to make a nuclear weapon has *not* been an important barrier, because even most poor countries could mobilize the modest amount of scientific and technical talent required to design and fabricate a fission bomb, given information available in the unclassified literature. (Making a fusion bomb -- a hydrogen bomb in popular parlance -- is much more difficult.)

Access to special nuclear material is now becoming easier, as a result of four factors: (1) the spread of small nuclear reactors designed for research but capable of producing modest quantities of plutonium usable for bombs; (2) the spread of commercial power reactors that produce large quantities of plutonium (enough for 10 or 20 bombs per reactor per year); (3) the spread of fuel reprocessing plants that can extract the plutonium from spent reactor fuel; and (4) the spread of uranium enrichment technology capable of producing bomb-quality material from natural uranium. (See also the discussions of these technologies in Chapter 8.)

The possibility of building a "research" reactor for the purpose of making plutonium for bombs is open to virtually any LDC that can persuade a DC to supply it with slightly enriched uranium for fuel (or with heavy water that permits the use of natural uranium as fuel -this is apparently

what India did). Fuel reprocessing technology good enough to extract a few bombs' worth of plutonium per year from the output of such reactors is not very difficult for even a small country to build. For small countries planning in advance to acquire a small nuclear weapons capability, the combination of a research reactor and small-scale reprocessing capability will probably remain the easiest route for some years to come.

The spread of commercial nuclear power reactors and related technology (mainly large enrichment and reprocessing plants) poses a somewhat different threat. These facilities provide countries not necessarily planning in advance to acquire nuclear weapons with an opportunity to do so very quickly if they should so decide. That a country embarks on a peaceful nuclear power program with the best of intentions is no guarantee that it will not take advantage of the nuclear weapons "fringe benefit" of its power program if circumstances change to make this seem advantageous. It seems certain that the spread of commercial nuclear power technology will accelerate the spread of nuclear weapons in this way; perhaps many recipient countries will not exercise the option to acquire weapons, but some surely will. [84]

Ownership of a large enrichment plant or large commercial reprocessing plant provides the greatest access to bomb-grade materials. Germany's sale of a reprocessing plant and an enrichment plant to Brazil and France's sale of a reprocessing plant to Pakistan therefore

[84] A good, concise discussion of the link between commercial nuclear power and proliferation is Allen L. Hammond, *Nuclear proliferation*, pt. 1, Warnings from the arms control community.

have justifiably generated a good deal of international concern, and much of the thinking about how to stem proliferation has focused on these two kinds of facilities. [85] One suggestion that has been made is to seek an agreement among the major industrial nations to expand enrichment capacity in cooperatively owned and operated facilities in the DCs; these consortia would offer low-enriched uranium (suitable for reactor fuel but not for bombs) to the members and to LDCs at prices too good to refuse, in exchange for plutonium-bearing spent fuel. The spent fuel would not be reprocessed anywhere for the time being, but instead would be stored at a few central locations in DCs, possibly to be recycled later in nuclear-energy centers having breeder reactors and a reprocessing plant clustered at a single well-guarded site. [86] Because France and West Germany expect to make a good deal of money exporting enrichment and reprocessing plants, they probably would not agree to this scheme unless it were accompanied by some sort of plan to divide up more equitably the world reactor market, which is now dominated by the United States. An even bigger obstacle is that the LDCs can hardly be expected to be more enthusiastic about complete dependence on DCs for uranium fuel than DCs are about dependence on OPEC for oil; one of the main ostensible reasons for wanting nuclear power, after all, is energy independence.

Of course, LDCs eventually will be able to build their own commercial fuel-reprocessing plants and uranium enrichment plants, and it is sometimes argued that this means it doesn't matter much what the United States or other DCs try to do now about proliferation. We disagree. It is true that all countries that want nuclear bombs *eventually* will get them, but it is essential to slow the

process as much as possible, in order to give the world political community as much time as possible to work out institutions and measures that will make the use of nuclear bombs less likely.

We are encouraged to note that recent major studies of the nuclear power question in the United Kingdom, Australia, and the United States have placed heavy emphasis on the weapons connection as the most serious liability of nuclear power. The September 1976 report of the U.K.'s Royal Commission on Environmental Pollution (known as the *Flowers Report* after its chairman, Sir Brian Flowers) held that:

. . . the spread of nuclear power will inevitably facilitate the spread of the ability to make nuclear weapons and, we fear, the construction of these weapons. . . . It has been argued that the possession of these weapons by the U.S.A. and the U.S.S.R. has been a powerful force for mutual toleration, but however true this is it would be folly to suppose that proliferation would necessarily lead to a similar balance and restraint in relations between other nations. Indeed, we see no reason to trust in the stability of any nation of any political persuasion for centuries ahead. [86a]

The *Flowers Report* concluded, with strong emphasis on the potential for misuse of plutonium by subnational groups as well as for proliferation, that the U.K."should not rely for energy supply on a process that produces such a hazardous substance as plutonium unless there is no reasonable alternative."

The Ranger Uranium Environmental Inquiry, convened by the Australian government to consider the wisdom of mining and exporting the substantial quantities of uranium at the Ranger site in that country's Northern Territory, concluded in its October 1976 report: "The nuclear power industry is unintentionally contributing to an increased risk of nuclear war. This is the most serious hazard associated with the industry." [86b] The Ranger report recommended that the decision to mine and sell uranium from the Northern Territory be postponed, that Australian policy should seek to limit or restrict expansion of the production of nuclear energy, and that no sales of Australian uranium should take place to any country not party to the NPT.

Finally, the March 1977 report of the Nuclear Energy Policy Study Group of the Ford Foundation in the U.S. observed that:

---

[85] See James J. Glackin, *The dangerous drift in uranium enrichment*; and Allen L. Hammond, *Nuclear proliferation*.

[86] For details of this and other proposals, see Abraham A. Ribicoff, *A market-sharing approach to the world nuclear sales problem*.

[86a] Sir Brian Flowers et al., *Nuclear power and the environment*.

[86b] R. W. Fox, G. G. Kelleher, C. B. Kerr, *Ranger uranium environmental inquiry*.

In our view, the most serious risk associated with nuclear power is the attendant increase in the number of countries that have access to technology, materials, and facilities leading to a nuclear

weapons capability. . . . If widespread proliferation actually occurs, it will prove an extremely serious danger to U.S. security and to world peace and stability in general. [86c]

The Ford group recommended that the U.S. defer the recycle of plutonium and the commercialization of the breeder reactor and that it seek "common supplier action to ban the export of such technology." It recommended also that the U.S. and other supplier nations provide assured supplies of slightly enriched uranium to other countries at favorable prices, a plan whose drawbacks we have already mentioned above. In April 1977, President Carter announced a nuclear policy for his administration essentially congruent with the Ford Study's recommendation.

While we applaud the progress represented by the positions taken by the Flowers, Ranger, and Ford reports and by the Carter administration's position, our own preference is for a stronger stance. We believe there should be an absolute embargo on the export of enrichment and reprocessing technology by any nation. [86d] The United States should cajole and, if necessary, coerce its allies into compliance, using every incentive and/or peaceful sanction at its disposal. (The possibilities are considerable, not least of which is the fact that West Germany and France will be dependent on U.S. enriched uranium for their own nuclear power programs into the 1980s.) Since the Soviets are also intensely concerned about proliferation, there is a chance that they would cooperate. Countries that have power reactors but no enrichment or reprocessing capability could be supplied with low-enriched uranium by the sort of consortium mentioned above, but there is reason to question whether any *additional* power reactors should be exported by anyone. A universal embargo on reactor exports may seem a drastic measure -- certainly drastic enough to require rewriting the NPT -- but lowering the probability of a nuclear holocaust is a desperately important task. The sort of pussyfooting that characterized attempts to stem proliferation before 1977 was not merely a scandal but a threat to the survival of civilization.

Chemical biological and environmental weapons. Even if humanity does manage to stop the proliferation of nuclear weapons, it still must deal with the ever-increasing deadliness of conventional weapons and the prospective horrors of chemical and biological warfare (CBW) and environmental warfare. Biological and chemical weapons, which could be nearly as destructive of lives as nuclear arms, seem to have some prospects of being eventually considered "conventional." [87] Environmental warfare is newer and potentially perhaps even more threatening. [88]

Achieving disarmament. The third element of difficulty in changing the rules of international relations is uncertainty about the best way to achieve disarmament and security in a world where in the past security has usually been provided by brute force, either threatened or overtly exercised. Unfortunately, the effort going into the study of peaceful means to world security has been infinitesimal compared with that going into military research, although almost no area needs greater immediate attention. The basic requirement is evident: once again it is a change in human attitudes so that the in-group against which aggression is forbidden expands to include *all* human beings.

If this could be accomplished, security might be provided by an armed international organization, a global analogue of a police force. Many people have recognized this as a goal,

but the way to reach it remains obscure in a world where factionalism seems, if anything, to be increasing. The first step necessarily involves partial surrender of sovereignty to an international organization. But it seems probable that, as long as most people fail to comprehend the magnitude of the danger, that step will be impossible. At the very least, societies

[87] J. P. Perry Robinson, *The special case of chemical and biological weapons*; see also Bo Holmberg, *Biological aspects of chemical and biological weapons*.

[88] For example, see Chapter 11 and Frank Barnaby, *The spread of the capability to do violence: An introduction to environmental warfare*; Jozef Goldblat, *The prohibition of environmental warfare*; and Bhupen dra M. Jasani , *Environmental modification: New weapons of war?*

must learn to weigh the risks inherent in attempting to achieve controlled disarmament against the risks of continuing the arms race. An attempt at disarmament could lead to a war, or to the destruction or domination of the United States through Chinese or Soviet "cheating." But, if disarmament were successfully carried out, and if an international police force were established, the reward would be a very much safer world in which resources would be freed for raising the standard of living for all people. [89] No problem deserves more intensive study and international discussion.

The dynamics of disarmament appear to be even more complex than those of arms races. Nevertheless, in 1970 the Arms Control and Disarmament Agency (ACDA), the only United States agency charged with planning in this area, had a budget of only a few million dollars (contrasted with $80 billion for "defense"). Representative John F. Seiberling of Ohio put it succinctly: "The Pentagon has 3000 people working on arms sales to other countries while the Arms Control and Disarmament Agency has 12 people monitoring arms sales. That gives you an idea of where the executive branch priorities are." [90] Moreover, the ACDA is heavily influenced by the Department of State bureaucracy, still a stronghold of cold-war thinking.

It has been suggested that an important step toward disarmament could be taken by the establishment of an international disarmament control organization, which would serve as a clearinghouse for information on the quantity and quality of weapons in various nations and would thus help to detect cheating on international agreements. [91] As a semi-independent United Nations agency, such an organization could play a vital role -- but so far there has been no significant effort to establish one.

Diverting the military to peaceful purposes. The fourth element of difficulty involves economics and the military establishment. Although this will be discussed in terms of the United States, there is every reason to believe that an analogous situation exists in the Soviet Union, the other military superpower. Civilians should realize that peace and freedom from tension are not viewed as an ideal situation by many members of the military-industrial-government complex. By and large, professional military officers, especially field grade and higher, hope for an end to

international tensions about as fervently as farmers hope for drought. When there is an atmosphere of national security, military budgets are usually small, military power minimal, and military promotions slow. The founders of the United States recognized that the military services were unlikely to work against their own interests, so they carefully established ultimate civilian control over the army and navy. It worked rather well for a long time.

But times have changed. Wars are no longer fought with simple, understandable weapons like axes, swords, and cannon. Now a nation needs weapons systems with complex and often arcane components, such as acquisition radar, VTOL fighters, Doppler navigators, MIRVS, cruise missiles, and nuclear submarines. Such systems cannot be produced rapidly, on demand, by a few government contractors. Long-term planning is required, involving not only the military services but also a large number of industrial organizations that supply various components.

Those organizations, not unnaturally, often hire retired military officers to help them in their negotiations with the government, where decisions on appropriations for armaments are made. The necessary intimacy of the military and industry in development and procurement of weapons led Dwight D. Eisenhower to coin the term *military-industrial complex*. The term *militaryindustrial-labor-government* complex sometimes seems more accurate. In his heavily documented 1970 book, *Pentagon capitalism*, industrial engineer Seymour Melman of Columbia University showed that even that term is inadequate to describe the Frankenstein's monster that has been created. [92]

This complex seems to have an aversion to peace, but it

---

[89] See, for example, Ronald Huisken, *The consumption of raw materials for military purposes*; and Ruth L. Sivard, *Let them eat bullets! The military budgets of the United States and USSR in 1973 were greater than the combined annual income of more than I billion people in thirty-three of the poorest nations and almost 20 times the value of all foreign aid from all sources*.

[90] Quoted in San Francisco *Chronicle and Examiner*, November 9, 1975.

[91] Alva Myrdal, *The international control of disarmament*.

[92] See especially Melman's chapter 7.

is not composed of a group of evil, conspiring people determined to napalm babies and keep the world poised on the edge of thermonuclear disaster. Rather, it is composed of people who, because of their personal histories and associations, are convinced that the only hope for survival of democracy lies in confronting the Soviet Union with overwhelming strength. On the other side, of course, their Soviet counterparts see Soviet preparedness as the only force preventing an attack by the capitalists, who want to destroy the Soviet way of life. The Soviets tend to forget that Americans did not attempt to destroy them when we enjoyed a nuclear monopoly. People in the United States, on the other hand, tend not to appreciate the valid roots of Soviet anti-Western paranoia. Members of both complexes are generally not long on introspection. Even though perpetuating the cold war adds to their own prestige and power, they do not see this as a major factor in their behavior. Indeed, many undoubtedly go to their jobs without thinking about why

they are doing them at all. In individual instances, however, it must be difficult even for members of the complex to avoid admitting the truth to themselves.

With the United States military budget now in the vicinity of $100 billion annually, it is not hard to find a quick $50 billion a year or so that might instead be used by the United States to try to save itself and the rest of the world. Melman, for example, showed how more than $50 billion could have been trimmed from the 1970 military budget without compromising national security. [93] Naturally, if huge cuts were suddenly made in military budgets, substantial economic dislocations and unemployment would occur, even if very careful planning preceded the cuts. Furthermore, it is probably politically unrealistic to expect the funds necessary for dealing with the world predicament to be diverted in great amounts from the U.S. military budget. Perhaps we should take Samuel Day's approach and, rather than cutting military budgets, give the army, navy, and air force new battles to fight. Day suggests declaring war on environmental deterioration and assigning the air force to police air quality, the navy to fight water pollution, and the army to "direct its martial spirit and organizational talents" to preserving the land -- perhaps by developing new energy technologies. [94]

The problem of breaking the power of the U.S. military-industrial-labor complex (and its analogues in other nations) and the related problem of finding a way to world peace are, obviously, among several major obstacles that must be overcome if civilization is to survive.

Two French scientists, Marcel Fetizon and Michel Magat, succinctly summarized the dilemma of modern warfare: "We must either eliminate science or eliminate war. We cannot have both." [95] One might go even further. Science and technology are incompatible with present human attitudes. Either the attitudes must change or science and technology will disappear, and one way or another most of *Homo sapiens* will go with them.

Conventional Arms

One of the unhappy facts of today's military situation is that while attention is focused on the nuclear arms race, a spectacular conventional-arms race has been going on relatively unheralded. The DCs in general and the United States and USSR in particular have been culpable in supplying vast amounts of arms to other nations. India and Pakistan, for instance, fought bloody wars in 1964 and 1973 with arms supplied by the United States to both sides. Needless to say, our military aid hardly helped those two LDCs toward development (although if the arms had not been obtained from the United States, the USSR, the United Kingdom, or France would gladly have supplied them).

George Thayer some years ago made a detailed study of the conventional arms trade. [96] His treatment was clearly not anti-American (or procommunist), and yet he felt constrained to state:

Still, today's arms trade is essentially an American problem. No nation talks more loudly about peace, yet no nation distributes as many weapons of war. No nation has spoken so passionately in favor of nuclear

[96]*The war business: The international trade in armaments*, p. 376.

controls, yet no nation has been so silent on the subject of conventional arms controls. Nor has any nation been as vocal in its desire to eradicate hunger, poverty, and disease, yet no nation has so obstructed the fight against these ills through its insistence that poor countries waste their money on expensive and useless arms.

Although military expenditures have peaked in the DCs, they are still skyrocketing in the LDCs -- among them, the countries least able to afford arms. If the DCs really believe their rhetoric about helping the LDCS, they should halt the flow of arms from DCs to LDCS. After Thayer's book was written, the Pentagon maintained that it had stopped vigorously promoting arms sales. Yet in 1974, U.S. sales were *8 times* the level Thayer had described, and double that of the Soviet Union. [97] The Soviet Union, France, and the United Kingdom have also been heavily involved in peddling weapons to LDCs. [98]

In addition there has been a trend toward supplying not obsolete but the most up-to-date arms, especially to oil-rich Middle Eastern countries, in an attempt to repatriate petrodollars. Iran, in particular, is being converted into a major military power. Another economic reason for the hucksterism is that the unit cost of procuring weapons systems drops with the size of the production run. For instance, the Pentagon hopes to sell as many as 3000 new YF-16 air-superiority fighter planes to other countries, thereby reducing the cost of their production to the United States Air Force and ringing up some $20 billion in sales (and needed foreign exchange). Should the United States be stupid enough to try to seize Middle Eastern oil fields, it might well end up fighting military forces equipped with the finest weapons its own technologists can develop!

As long as the excuse can be given that, if the United States refrains from selling the weapons, the French, the Swedes, or the Soviets will sell them, and as long as such sales are believed to be needed to counterbalance the petrodollar drain, the Pentagon will probably continue to sell arms. The rewards for doing so appear too much greater than those of striving for multilateral controls or, heaven forbid, unilaterally refusing to accept blood money on the basis of principle. Presumably, the Pentagon is confident of its ability to cope with any potential danger to the United States posed by unstable Third World countries that are armed to the teeth.

HELPING THE POOR: A PROBLEM IN ETHICS

Assuming human society for the next quarter-century somehow manages to avoid a nuclear conflagration -whether by disarming, by containing nuclear proliferation, or just by committing itself to peace through negotiation -- all the other elements of the human predicament remain. It is becoming clear that human beings, and particularly thoughtful people in the rich nations, are now faced with some long-avoided ethical questions that can no longer be ignored. They concern

such matters as the distribution of wealth, the exploitation of one group of people by another, the responsibility of those now living for the acts of their forebears and for the legacy of their descendants, and the duties of the provident toward the improvident.

Perhaps the most difficult of all are the questions about what might be called intergenerational equity. Is it ethical, for example, for this generation to create radioactive materials that future generations must guard or beware of? Can people alive today ethically risk the capacity of the planet to support future generations in order to provide themselves with highly affluent lives? Is there any way that actual deprivation today can be balanced against hypothetical deprivation in the future? What are the ethics that govern life-and-death decisions in the face of uncertainty? Unfortunately, traditional human value systems, which evolved in a relatively steady-state world, provide little guidance in questions of intergenerational equity.

Such ethical issues and how this generation resolves them (or fails to resolve them) will have profound consequences for our future and those of generations to come. We cannot provide definitive answers to these

---

[97] J. W. Finney, *Arms Sales, a real growth industry*. An even more recent source shows no decline in the pace of arms peddling by the Pentagon (Michael T. Klare, *The political economy of arms sales*). President Carter has expressed concern over the problem, but whether his administration will succeed in reversing the trend against powerful economic interests remains to be seen.

[98] Anne H. Cahn, *Have arms, will sell*.

questions, of course; they must be debated and discussed widely. But we feel that people must be made aware not only of the ethical meanings of the judgements they make but of their practical consequences and implications. At the same time, defining an ethical position -- whether as an individual or as a nation -- is essential to identifying attainable goals. If this generation can reach an informed consensus on the kind of world society it hopes to have a century or two centuries hence, it can meet its problems with a coordinated response rather than simply lurching from crisis to crisis and fighting among groups over the solution to each one. As we have pointed out, failure to institute reform when it is needed is also action that has consequences.

The issues of wealth, exploitation, responsibility to future generations, and many others as well, are all related to philosophical questions that have long puzzled human beings. The most fundamental of those questions probably is, What is the value (or purpose) of human life? Some people, believing that human life in itself has enormous value, would like to maximize the number of human beings alive at any given time. A Brazilian economist at a United Nations meeting in late 1973 stated explicitly that he thought humanity's goal should be to have the maximum number of people existing at the minimum standard of living. (To his credit, he did not fall into the common logical trap of simultaneously attempting to maximize both numbers and living standards!) He also stated his reason for promulgating that goal: "Because I was glad to be born." [99]

Our view is that it would be better to have half a billion people leading comfortable and secure lives than 20 billion living at die fringes of existence. But our view -that human life has whatever value people give to it -- is no more defensible scientifically than that Brazilian's view. Society could promote the existence of the maximum number of people, or it could strive for the maximum standard of living (however measured) for each person. About all that one can say with assurance is that attempting to do either in one generation would have profound consequences for future generations.

Questions about the value of human life are made more complex by the genetic, social, political, and economic diversity of *Homo sapiens*. Just ask the following questions of some of your close friends and see how different the answers are even within a single group: "How much social and personal effort should go into equalizing incomes, opportunities, and attitudes within and among nations?" Or, to put it another way, "Would the world be better off if everyone were the same height, color, and personality, and if they all had the same income and social status?"

Some people might answer the second version yes, because they think uniformity would do away with class distinctions, racism, and war. We would say no -- in part because *Homo sapiens* shows a strong tendency to invent differences where natural ones do not exist, but, more important, because we believe that biological and cultural diversity, in addition to adding interest to human life, provide humanity with the flexibility necessary to adjust to changed conditions and thus avoid disaster. Of course, diversity of income is easy for the affluent to espouse, and extolling genetic diversity could be an excuse for maintaining a supply of underdogs to do menial tasks. One of the critical questions facing humanity may be whether or not a satisfactory balance can be struck between equality and diversity.

With those philosophical issues in mind, let us turn to two practical issues coming into sharp focus as the age of scarcity commences: *lifeboat ethics* and *triage*.

Lifeboat Ethics

The ethics of aid-giving have been examined by Garrett Hardin with the logical rigor that those who know the other writings of that outstanding biologist have come to expect and cherish. Moving on from his classic analysis of the "Tragedy of the commons," Hardin examined the options open to the rich nations with respect to sharing with the poor and compared each rich nation metaphorically to a lifeboat with a load of comparatively rich people. [100]

The poor of the world are in other, much more crowded lifeboats. Continuously, so to speak, the poor fall out of their lifeboats and swim for a while in the

[100] *Living in a lifeboat*.

[99] We immediately asked him if he would have been sorry if he had not been born!

water outside, hoping to be admitted to a rich lifeboat, or in some other way to benefit from the "goodies" on board. What should the passengers on a rich lifeboat do? This is the central problem of the "ethics of a lifeboat."

Hardin then examines what the passengers of a lifeboat of limited carrying capacity (and perhaps filled to 80 percent of its capacity) can do about those still swimming. One option is to take aboard all of the needy -- until the lifeboat is swamped and all drown: "Complete justice, complete catastrophe." A second option is to take on enough people to fill the remaining carrying capacity, sacrificing any safety factor represented by that excess capacity. But then the critical problem of how to choose those to be saved rears its ugly head. A third option is to admit no more to the boat, preserve the safety factor, guard against boarding parties, and assure the survival of the passengers.

That the last option is unjust, Hardin admits. Those who feel guilty, he points out, can change places with those in the water. Those willing to climb aboard obviously would have no such qualms, so the lifeboat would automatically purge itself of guilt as the conscience-stricken surrendered their places.

Hardin does not, of course, restrict himself to the metaphorical analysis. He dwells on the finite nature of Earth and of the resources of each nation (the limited carrying capacity of the lifeboats), the much more rapid population growth among the poor than the rich, and the suspect motivations and dismal results of aid programs so far attempted. He claims, "Every life saved this year in a poor country diminishes the quality of life for subsequent generations," a claim that may well be correct. He argues strongly that "well-meant sharing of food in a world of irresponsible reproduction" promotes catastrophe, and he suggests that the United States reduce immigration to the point where births plus immigrants balance deaths plus emigrants (that is, to ZPG). He concludes that, in the absence of a world government capable of controlling human reproduction worldwide, survival with dignity demands that we practice the ethics of the lifeboat.

We share with Hardin the sense that assistance to nations without population control may do no good and may do great harm. We do believe that it is possible, however, to supply assistance that will both improve the lot of the recipients and help to depress birth rates, although we admit to being extremely pessimistic about whether such aid will ever be given or whether in many areas it can be given in time to avoid further disaster.

Our greatest disagreement with Hardin comes not in the analysis of lifeboat ethics within his framework, but with the metaphor itself. In order for it to be sufficiently realistic to apply to today's situation, some changes would have to be made in the image. For instance, there would have to be a flow of rations between the lifeboats, in which the rich lifeboats regularly took more than they gave. And the rich lifeboats would have to be dependent on the poor for all sorts of materials they needed to maintain their affluence, materials not found among their own original provisions. Furthermore, the rich passengers on the lifeboats would have to be engaged in wasting their survival rations, while the poor would have none to waste. (Hardin's statement about saving lives in poor countries is even more applicable to the rich. Every life preserved in the United States threatens the resources and environment of the planet many times more than a

life preserved in, say, Bangladesh). And finally, the people in the poor lifeboats should be energetically arming themselves with nuclear and biological weapons in an effort to present a credible threat to the rich. [101]

We think, therefore, that there are strong practical as well as ethical reasons for changing behavior in the rich lifeboats before adoption of a strict lifeboat ethic should even be considered. At the very least, elimination of resource waste and of dependence on poor countries for raw materials seem to be required before the metaphor could be applied. It seems likely, however, that the rich nations will be forced to cut down their waste of resources and perhaps to reduce their imports from the LDCS, whether they want to or not. Even so, the fundamental interdependence of nations is unlikely to disappear. Nor is the peril of nuclear or chemicalbiological conflict, the chances for which would surely be enhanced by a refusal of rich nations to assist nations in need. Finally, there is no evidence that the American

[101] For another critique of lifeboat ethics, see W. W. Murdoch and A. Oaten , *Population and food: Metaphors and the reality*. Further discussion of these issues can be found in "Comments", *The Ecologist*, vol. 8, nos. 6 and 8 (August and October), 1976.

public is yet hardhearted enough to watch children starve on their television news programs without offering help. C. P. Snow predicted such news stories in 1968 and they came to pass in the early 1970s during the Sahel famine. The impact on the conscience of the United States public was considerable and doubtless helped accelerate American aid efforts.

Triage

If it is granted that the rich countries must make some effort to help poor countries (whether on moral or practial grounds), then the issue becomes one of deciding how to allocate the funds, food, or whatever is needed. This is particularly a problem if there is not enough to go around.

William and Paul Paddock, in their 1967 book *Famine -- 1975!* predicted a deteriorating world food situation in the 1970s and considered the difficult question of how the United States might allocate the limited food that would be available for foreign aid. They proposed a policy based on the concept of *triage*, a term borrowed from military medicine. Briefly, the idea is this: when casualties crowd a dressing station to the point where all cannot be cared for by a limited medical staff, some decisions must be made on who will be treated. All incoming casualties are placed in one of three classes. In the first category are those who will survive regardless of treatment; in the second are those who can be saved, but only if they are given prompt treatment; and in the third group are those who will die regardless of treatment. When medical aid is severely limited, it is concentrated on the second group alone; the others are not treated.

The Paddocks suggested that the United States devise a similar system for classifying nations in need of help. Some countries would be able to maintain selfsufficiency without enormous outside aid. They would be ones with abundant resources to trade for foreign purchases (OPEC nations, for example) or with efficient governments, strong population-control programs, and

strong agricultural development programs. Although our aid might help them, they could get along without it. The Paddocks suggested that Libya was probably such a country because it had the resources, in the form of oil, that would allow it to purchase food as its population expanded.

Some nations, on the other hand, might become self-sufficient if they were given some food to tide them over. The Paddocks thought that Pakistan -- at least West Pakistan -- might have been such a country. Considering the recent history of that nation, however, we wonder if they were not too optimistic.

Then there is the last, tragic category: those countries so far behind in the population-food race that there is no hope that limited food donations could see them through to self-sufficiency. The Paddocks felt that India, among others, was probably in this category. Bangladesh is today a more clear-cut example. [102]

In a situation where LDC needs for free or low-cost food imports might greatly exceed what was available, the Paddocks recommended giving food only to those countries it would really help -- the second category. The first group might suffer a few lean months or have to sacrifice foreign exchange to buy food but would be in no danger of starvation. The third group would suffer greatly from famine, but giving aid needed just as badly elsewhere would only postpone the inevitable in such hopeless cases.

When the book was published, many people declared the Paddocks' proposal immoral, while others ridiculed their prediction of famine in the mid-1970s. After all, the Green Revolution was going to banish famine forever!

That the Paddocks' predictions on famine were accurate is now history, and the onset of famine on the Indian subcontinent in 1974, following on the heels of several years of famine in the Sahel, brought renewed attention to the idea of triage. [103] By then, however, the question seemed largely moot. The United States no longer had vast grain surpluses it was willing to give away, and it was allocating its food aid not on the basis of recipients' needs, but mainly on the basis of what the United States government perceived as its own political interests. Hence, the bulk of American food aid went to the U.S.-supported regimes in South Vietnam and Cambodia in 1974 and the beginning of 1975.

Although the precise situation in which the Paddocks envisioned triage's being applied no longer holds, ethical

[102]Kushwant Singh, *The international basket case*.
[103]Wade Green, *Triage*,

questions associated with the allotment of limited aid seem certain to be raised repeatedly in the future. Assuming that rich nations will (and should) transfer food and other aid to the poor, and further assuming that such transfers may not be sufficient to meet all the needs of the poor, the

rich nations -- especially the foodexporting ones -- are confronted with some rather unpalatable alternatives. [104]

First, they could continue to do what they have been doing: allot aid largely on the basis of perceived selfinterest with a little humanitarianism blended in. This is the course of least resistance. It has accomplished little in the past except to create enmity among recipients, and it promises little more for the future.

Second, they could attempt to spread their aid "evenly" among all the needy (whose numbers are rapidly increasing), realizing that it is doing no good but appeasing those who consider this the only ethical course.

Third, they could practice some form of triage, based purely on perception of need and potential for attaining self-sufficiency. This would be an immoral policy in the view of some observers, who would say, "What gives the United States (or Canada, or Australia) the right to decide who lives and who dies?" Of course, since the ethical questions surrounding triage start with the assumption that available aid is inadequate to help everyone but could help some, any of the above approaches would amount to playing God; the only difference would be in the outcome.

Finally, the rich countries can avoid the dilemma by donating their assistance funds or commodities to international "banks," leaving the distribution to committees of the whole composed of the potential recipients. This course has considerable merit, and indeed aid is increasingly being allocated in this way. The World Food Council is a case in point, as its allocations of donated food are determined by a mixed committee of donor and recipient countries, in which the recipients are the majority. Similarly, bilateral assistance is being replaced by funding both direct assistance and loans through the World Bank and various regional development banks.

Representatives of recipient nations have been gaining greater voice in determining allocation in recent years. Whether this change will result in the aid's going where it will do the most good remains to be seen; past performance of people from LDCs in positions of power suggests they are no more generously endowed with wisdom or fairness than are people from DCs. But at least the developed countries cannot be blamed for administrative failures if the decisions have been made by people from LDCS. Although donors of foreign aid understandably do not wish to see their assistance wasted, they must learn to take that chance (after all, a not inconsiderable amount has been wasted when they controlled the purse strings). If a recipient country blatantly abuses aid in the view of its peers in a development agency, future assistance funds can be denied.

Regardless of how development resources are allocated, care must be taken to keep large bureaucratic organizations such as the U.S. Agency for International Development (AID) and the World Bank under continuous scrutiny. Like all such institutions, they have vested interests in "success" and in their own perpetuation. The record of AID in the past, for instance, has been mixed, to say the least. [105] The abuses found in 1975 and 1976 in the grain shipping business in the United States -including shipment of short weighted and contaminated grain -- are another example. Careful oversight and independent evaluation of all national and international agencies and assistance programs are needed now. And if the amount of development assistance is

increased in future years, as it clearly should be, it will become even more essential to safeguard the implementing organizations against abuses and inefficiency.

INVENTING A BETTER FUTURE

The orientation of hope is toward the future; even in the darkest hours forces emerge which make a new future possible. We have not reached the point of no return. What holds men back is not the pressure of reality but the absence of dreams. If enough people could come to see

[104]For a discussion of such alternatives and the food producers' responsibilities, see Lester R. Brown, *The politics and responsibility of the North American breadbasket*.

[105]For critiques, see W. and E. Paddock, *We don't know how: An independent audit of what they call success in foreign assistance*; and Karen De Young , *Selling the Sahel*.

their present predicament and the possibility of a new way into the future we could make the first step into the new world. We need in practice the moral equivalent of war to direct our purposes and mobilize our endeavours just to make the next step one that is in the right direction.

One sort of world is dying. Another is struggling to be born. We may not be able to predict the future. We can invent it.

-- Charles Birch, *Confronting the Future*, 1975

If it is generally agreed that all nations on Earth are becoming increasingly interdependent and must cooperate to create what has been called a human community, [106] how is this to be accomplished? We have examined many of the dangers that lie ahead, inevitable or potential, and discussed some of the wrong choices that have been made in the past. What new, realistic goals can now be held up that all humanity can agree on and strive toward? What choices -- in development policy, in managing the world resource commons, in narrowing the rich-poor gap -- will help humanity attain those goals?

Obviously these are questions that must be decided by an informed consensus among all nations, but we will add to the dialogue some suggestions of our own. In our opinion, major changes must occur in the three intertwined areas of foreign aid, development goals, and international politics.

What Rich Countries Can Do

The rich must live more simply so the poor may simply live.

-- Charles Birch, *Confronting the Future*, 1975

All the rich nations must by now recognize that their fates are inextricably bound up with those of the LDCs -- the OPEC oil cartel and the Indian A-bomb should have made this crystal clear. They must further recognize that their accustomed patterns of using resources cannot continue much longer -- if depletion and rising prices fail to force a change, militant LDCs may succeed. Political and economic realism and any sense of fair play dictate that measures must be taken to effect some form of redistribution of the wealth of the world. In other words, rather than abandoning efforts to help poor countries, the overdeveloped rich world should be *increasing* those efforts.

Transferring wealth. Two scientists, Lord Snow of the United Kingdom and Andrei D. Sakharov of the USSR, made rather similar proposals along this line some years ago. Sakharov, "father of the Russian hydrogen bomb" and one of the youngest men ever elected to the Soviet Academy of Sciences, in 1968 expressed his views in an extraordinary document entitled, *"Progress, Coexistence, and Intellectual Freedom,"* which was not published in the USSR. Among his many proposals was that, after the United States and the USSR have "overcome their alienations," they should collaborate in a massive attempt to save the LDCs. This attempt would be financed by contributions to the effort from the DCs of 20 percent of their national incomes over a fifteen-year period.

Lord Snow, an eminent physicist and novelist, supported Sakharov's suggestion. He recommended that the rich nations devote 20 percent of their GNPs for ten or fifteen years to the task of population control and development of the poor countries. [107]

Both proposals called for a transfer of wealth roughly 10 *times greater* than that represented by the oil price increase and traditional foreign aid combined. [108] We believe an effort of this magnitude is not only justified but essential. By the scale of the effort, and by its no-strings-attached nature (a substantial portion should be channeled through international agencies under control of LDCs), the people of the less developed world might be convinced that those in the developed countries *do* care. Though there is much suffering today in the LDCs (and more is clearly unavoidable), a substantial lowering of DC-LDC tensions could occur if the LDCs

[106] John Richardson, Jr., Preparing for a human community, news release, *U.S. Department of State*, Washington, D.C., May 18, 1976.

[107] Lecture given at Westminster College, Fulton, Missouri, November 12, 1968. Reprinted in the *New York Times*, November 13, 1968.

[108] Foreign aid from DC governments and OPEC amounted in 1973 to about $15 billion out of a world product of perhaps $5000 billion. Another $1.4 billion went through private agencies, of which about $1 billion was spent in the United States (Sommer, U.S. voluntary aid).

felt that help was really on the way. And, of course, the joint DC effort could help to bring about that community of feeling generally regarded as essential to the abolition of war.

This brings us to the question of what changes in the DCs might be made to permit such a transfer of wealth? Some people seem to believe that all that would be required is for the rich to

change their lifestyle and consume only as much as the average human being. Then the wealth saved could be transferred to the poor, raising them to the average. But income is closely tied to productivity. As Nathan Keyfitz observed, "If, starting tomorrow, Americans were all to live like Indians, then their higher incomes would simply disappear. There would be nothing to transfer. How much is transferable depends on the extent to which Americans could consume like Indians while continuing to produce like Americans." [108a] Some way therefore must be found to free wealth and transfer it without breaking the close link between production and consumption.

De-development of Overdeveloped Countries

The proper object of economic activity is to have enough bread, not infinite bread, not a world turned into bread, not even vast store houses full of bread. The infinite hunger of man, his moral and spiritual hunger, is not to be satisfied, is indeed exacerbated, by the current demonic madness of producing more and more things for more and more people. Afflicted with an infinite itch, modern man is scratching in the wrong place, and his frenetic clawing is drawing blood from the life-sustaining circulatory systems of his spaceship, the biosphere.

-- H. E. Daly, 1973

In a sustainable world with a more just distribution of wealth, a nation is over developed when the citizens of that nation consume resources and pollute the common environment at a rate which is greater than would be possible for all the people in the world.

-- Charles Birch, *Confronting the Future*, 1975

The most critical change of all must be a change in goals; all people, rich and poor alike, must come to recognize that being a citizen of a giant, smoggy, freeway-strangled industrial state is not necessary to being a happy, healthy, fulfilled human being. For by Birch's definition and several other criteria, the industrial nations, which the world has become accustomed to calling DCs, are really *overdeveloped countries* (ODCs).

Today the trinkets of industrial civilization have the strongest appeal to the naive, both within and outside industrial society. If DCs continue to train their own people to think of the power lawn mower and automatic icemaker as the finest achievements of humanity, it seems unlikely that the rising expectations of the LDCs will rise above them either. But if we in the United States (and Europeans, Soviets, Japanese, Canadians, and Australians) can learn to recognize and attempt to correct our own errors, then perhaps people in the LDCs will see their way clear to establishing new goals -- development within resource limitations and with careful attention to the *quality* of life.

It is therefore apparent that one key to saving world society lies in a measured and orderly retreat from overdevelopment in today's ODCs -- a process we will label, for want of a better word, *de-development*. If the ODCs can successfully move toward spaceman economies, systematically eliminate the wasteful, frivolous, and ecologically harmful aspects of their behavior, shift the economic emphasis to Type I GNC (Chapter 14), and divert their excess productivity and technological expertise into helping the poorer people of the world rather than exploiting them, then perhaps the citizens of the poor countries will accept a different kind of development -- what we call *grass-roots development* -- as their most desirable goal. On the other hand, if the ODCs continue to loot the world of its high-grade resources, use their technology to produce doomsday weapons and senseless gadgets for superconsumers, and permit the gap between the rich and the poor to continue to widen, it seems certain that the people of the LDCs will continue to strive toward over-development themselves.

As we see it, de-development of the ODCs should be given the top priority. Only when that course is firmly established, will there be any real hope for all of humanity to generate a worldwide spirit of cooperation

---

[108a]Nathan Keyfitz, World resources.

rather than competition and to plan the development of our spaceship with the holistic perspective that is so essential to the survival of civilization. Only then can consumption in the LDCs be linked both psychologically and physically to production in the ODCs and a substantial transfer of wealth accomplished.

In short, the DCs must not only give unprecedented aid to the LDCs, they must help the LDCs avoid the mistakes made by the DCs. Something like this message must come across:

By making the fundamental error of basing our standard of progress on expansion of material throughput, we have created a vast industrial complex and great mental, moral, and aesthetic poverty. Our cities are disaster areas, our air often unbreathable, our people increasingly regimented, and our spirit increasingly domitable. We require far too large a slice of the world's resources to maintain our way of life. We, in short are not developed, we are *overdeveloped*. We now realize that our current patterns of consumption and resource exploitation cannot and should not be sustained. While we are correcting our mistakes and de-developing, we want to help you develop your nation -- not in our image, but in whatever way is most appropriate for your culture. And we hope that this development will start at the grass roots level to improve the quality of life for your poorest people.

It must be clearly recognized that *development* in the minds of a great many people means the industrialization of the globe, and that the material culture of the West seems to have a nearly irresistible appeal to most human beings. Whatever value judgements one might wish to make about this are probably immaterial -- since the planet almost certainly cannot support even 4 billion people with the material throughput per person associated with, say, the United States or West Germany today. The task thus becomes one of diverting people from pursuing that

material-intensive and environmentally unsustainable lifestyle. The only way to divert the rush in the LDCs to mimic overdevelopment is to change the model -- to trim from the lifestyle and supporting technology of the ODCs their energetic and material profligacy while increasing the quality of life. That is the essence of de-development.

Harnessing technology. The whole idea of dedevelopment has met with considerable misunderstanding and resistance, and will undoubtedly meet with much more. Some people have mistakenly assumed that the idea of de-development is basically antitechnological. The emotion that accompanies resistance to de-development is exemplified by the reaction of physicist Alvin M. Weinberg, who wrote that the de-development message was "we should destroy technology since technology got us into this dilemma, and this will set things right." [109]

This is certainly not what we mean by de-development. Instead, technology must be brought under control and turned to the service of humanity. Technology is essential to de-development, but as de-development proceeds, society must be more discriminating in the use of technology and much more cautious about its potentially disastrous side effects. Emphasis should be shifted to maximizing efficiency, learning to get more from less. Technology should be used to further human goals other than satisfaction of the desire for material growth. Technologists must learn the physical and biological limitations of their discipline and be prepared to put social limitations on its use.

But to turn away from technology itself would be to condemn to death many hundreds of millions of people now living on this overpopulated planet. The fullest use of technological expertise will be needed to maximize agricultural production, while minimizing the destructive effects of agriculture on the ecosystems of the planet. New technologies must be developed for recycling materials, for controlling pollutants, for efficient transport systems, and for population control. Efficiency in power generation from fossil fuels must be increased in order to buy time for developing new technologies for the generation of power. Technologies will be needed at all stages to help in the transition from a cowboy to a spaceman economy; technology will play a key role in the processes of both grass-roots development and de-development.

Angry opposition to de-development can be expected from some technologists who are used to having their schemes for progress accepted without question by a dazzled public. SSTs space colonies, thermonuclear weapons and delivery systems, geodesic domes over

[109] *BioScience*, April 1, 1971.

cities, fission power, giant automobiles, plastic wrappings, genetic engineering, disposable packages and containers, synthetic pesticides, and the like are supposed to be accepted as self-evidently desirable. However, many technologists now correctly perceive that, if the ODCs are to be de-developed and civilization is to persist, the halcyon days of unquestioning public acceptance of technological "progress" must disappear forever.**Energy and prosperity.** Civilization is not running out of energy; but it is running out of cheap energy, out of environmental tolerance for disruptive energy technologies, and out of time in which to do

something about it. [110] The global dilemma that is emerging from this situation has three main elements.

1. Energy is an indispensible (necessary but not sufficient) ingredient of prosperity. The prospects for prosperity of nations presently poor, and of the poorer segments of rich nations, are threatened as the price of this indispensible commodity rises.
2. The technologies of energy supply, conversion, and application are dominant ingredients of civilization's disruption of the global environment. (Chapter 8, Chapter 10, Chapter 11).
3. High rates of growth of energy use in the rich countries, where total use is already very high, compound the foregoing problems. Rapid growth on top of an already large base becomes increasingly troublesome economically as the base gets ever larger:
    a. Supplies of capital for building new facilities are strained, so capital itself becomes more expensive.
    b. Such cheap energy resources as remain do not suffice, so more expensive ones are tapped.
    c. The world market price of even the cheaply extractable resources rises to equal that of the expensive supplements, so poor countries can no longer afford to pay even for their present pathetic share of the world energy supply, and rich countries experience serious problems of inflation and balance of payments.
    d. In desperate attempts to sustain rapid growth and increase self-sufficiency, firms and nations gamble ever larger stakes on unproven energy technologies, some likely to fail expensively. The same hasty technological gambles, forced by a high growth rate on a large base, greatly increase the chance and probable magnitude of serious environmental mistakes.

No policy or combination of policies can deal successfully with these problems unless it incorporates as a central element a sharply reduced rate of growth of global energy use. Overconsumption in the richest countries and the legitimate needs of the poor countries dictate that this reduction be accomplished by an even sharper slowdown in growth of energy use in the rich countries, where most use now takes place.

Table 15-3 compares the rates of energy use in the United States, other ODCS, and LDCS. The lower part of the table shows annual growth rates in population and energy use in the early 1970s. Some hint of the problems implied by continuation of these trends may be obtained, for example, by extending the 5-percent annual rate of growth in total energy use through the year 2020, accompanied by population growth rates of 1 percent per year in the rich countries and 2.5 percent per year in the poor ones. The result is 8.3 billion people in LDCS, with an average annual energy use of 1.66 thermal kilowatts per capita and 1.9 billion people in ODCs with an average annual per-capita use of 34.3 thermal kilowatts. The worldwide total annual energy use would be 80 billion thermal kilowatts, more than 10 times the 1972 figure.

An even worse outcome would ensue if attempts were made to raise the energy consumption of the LDCs to match the moving target of rapidly increasing energy consumption by the ODCS. Not only would the gap between them not be closed, but the world economy and the environment would be wrecked in the attempt.

But there is an alternative. It is easily shown that a dramatic slowdown in the growth of energy use in the rich countries would permit, in principle, an *acceleration* of the growth of per-capita energy use in the poor countries within a context of *slackening global growth*. In this way the wide rich-poor gap in energy use, which

[110]This section is based on John P. Holdren, *Energy and prosperity: Some elements of a global perspective*.

roughly parallels the rich-poor gap in well-being, could begin to be narrowed. (As we have noted, of course, much attention must also be given to the other aspects of socioeconomic development, without which energy alone cannot produce prosperity.) The slower rate of growth in total global energy use, and the much slower growth in the rich countries, where certain environmental impacts of energy technology are now most severe, would significantly reduce the grave environmental risks that accompany continuation of past trends.

The success of such a scheme would depend heavily on the success of population control. Only if population growth rates were very much reduced could the high growth in per-capita energy use needed and desired in the LDCs be achieved within an economically and environmentally sustainable rate of total growth. In the rich countries, the effect of multiplying even quite small population increments by the very high per-capita energy use already prevailing there makes it essential for them to approach zero population growth as soon as possible.

A specific scenario illustrating how the bulk of growth in energy use might be diverted from rich to poor countries, while population growth is slowed, is outlined in Table 154.

The rates of population growth and per-capita energy use indicated in the four intervals of time are optimistic but not physically impossible. Until 1980 the growth of per-capita energy use in both rich countries and poor ones represents only a moderate reduction from recent trends, and the average rates of population growth in this period are unchanged from recent values.

The steady decline of ODC population growth to zero over the subsequent two decades seems not entirely implausible, in view of declining fertility rates already being experienced in the United States, Europe, and elsewhere. The reductions shown in population growth in the poor countries between 1980 and 2020 would require consensus and enormous effort, as we have emphasized earlier, but it may be possible.

There is no question that growth rates in per-capita energy use as large as those shown in the table for the LDCs between 1990 and 2020 are possible in individual countries for limited spans of time. But achieving those atwages throughout the less developed world for thirty

TABLE 15-3 Global Energy Use (1972) and Rates of Change (late 1960s and early 1970s)

	United States	**Other ODCs**	**LDCs**
DISTRIBUTION			

	United States	Other ODCs	LDCs
Population (billions)	0.2	1.0	2.5
Per-capita energy use (kwt)	12.0	3.7	0.5
Total energy use (billion kwt)	2.4	3.7	1.3
% of global energy use	33.0	50.0	17.0
ANNUAL GROWTH RATE (%)			
Population	0.7	1.0	2.5
Total energy use	5.0	5.0	5.5
Per-capita energy use	4.3	4.0	3.0

Note: Energy consumption is given as the equivalent continuous rate, in thermal kilowatts (kwt), excluding food, dung, and some wood used for fuel. (A consumption of 24 thermal kilowatt hours per day corresponds to the equivalent continuous rate of I thermal kilowatt.)

TABLE 15-4 A Scenario for Redistribution of Growth in Energy Use

	ODCs		LCDs	
	Population	Per-Capita energy use	Population	Per-Capita energy use
POSTULATED AVERAGE GROWTH RATES IN SPECIFIED PERIODS (%)				
1972-1980 *	1.0	3.0	2.5	2.5
1980-1990	0.7	1.0	2.0	3.5
1990-2000	0.3	0.5	1.5	4.5
2000-2020	0.0	0.2	1.0	4.5
VALUES AT SPECIFIED TIMES (POPULATION IN BILLIONS, PER-CAPITA ENERGY USE IN KWT)				
mid- 1972	1.20	5.25	2.50	0.50
mid- 1980	1.30	6.65	3.05	0.61
mid- 1990	1.39	7.35	3.72	0.86
mid- 2000	1.44	7.72	4.31	1.33
mid- 2020	1.44	8.03	5.26	3.20

Total energy use in 2020 = 28.4 billion kwt.

Total population in 2020 = 6.7 billion.

Average annual rate of growth in total energy use, 1972-2020 = 2.8%.

*Measured from midyear to midyear.

Source: John P. Holdren, *Energy and prosperity*.

years would be a formidable task, requiring a transfer of technical resources and capital from the rich countries to the poor ones of the magnitude envisioned by Sakharov and Snow.

If such a transfer of wealth could be effected, by whatever means, [110a] the results would be quite remark-

[110a] One possibility that has been proposed is to tax nonrenewable resources exported from LDCs to ODCs, including fossil fuels (Julian Lessey, Taxes for conservation). This would have the effect simultaneously of reducing consumption in ODCs and providing funds for development in LDCs.

able. The total rate of energy use by a world population of 6.7 billion people in 2020 would be about 28 billion thermal kilowatts, or 4 times the 1972 rate instead of more than 10 times. Average per-capita energy use among the 5.3 billion people in LDCs would roughly equal the 1972 rate for Japan or Austria, and the average per-capita energy use of the 1.4 billion people in all ODCs would be about that of the United States in the early 1960s.

It is far from certain, of course, that 4 times the 1972 rate of energy use could be managed in 2020 without grave environmental problems, just as it is not clear that 6.7 billion people could be fed and provided with other raw materials for a decent existence without undermining essential environmental services. Nevertheless, there is perhaps a chance for success, particularly with the degree of international cooperation that might emerge from a substantial narrowing of the rich-poor gap. There is *no* chance if past trends continue.

Success will require, in addition to the sort of drastic reallocation of growth just described, great emphasis on promoting those technologies of energy and materials supply that generate the least environmental disruption, and on phasing out those that pose the greatest threats of irreversible ecological or social harm. Solar energy has great promise in the first category, for instance; whereas nuclear fission deserves careful scrutiny as to whether it belongs in the second.

A final essential ingredient of this scenario would be a major, coordinated, worldwide campaign of research, development, and implementation aimed at increasing the amount of prosperity derived from each unit of energy (and, indeed, from each unit of other raw materials). (See Chapter 8 and Chapter 9.)

Tailoring technologies of energy supply and application to specific regional conditions might avoid in the LDCs much of the needless energy waste that now prevails in the ODCs. [110b] By maximizing the benefit derived from each increment of energy use, while minimizing the undesirable side effects, prosperity in the poor countries surely could be increased faster than the rate of growth of energy use itself. Even in rich countries, where a drastic slowing of growth in energy use is clearly called for, ingenuity could reduce the impact of rising energy costs and environmental destruction and brighten the prospects for an increase in actual well-being. Such transitions would unavoidably pose some economic problems, but they are likely to be much less severe and more temporary than the growing economic problems of maintaining the status quo. Indeed, the evidence is mounting that proceeding along the present course is *physically* impractical as well as socially unacceptable and politically perilous. Viewed in that context, the above scenario, utopian as it may seem at first, appears as plain common sense.

What Poor Countries Can Do

The man who holds that every human right is secondary to his profit must now give way to the advocate of human welfare.

-- Theodore Roosevelt

No race can prosper till it learns that there is as much dignity in tilling a field as in writing a poem.

-- Booker T. Washington

A large-scale effort on the part of the ODCs to transfer wealth and resources to LDCs will not suffice, however, unless there are basic changes in the value systems related to development. If industrialization of the entire world is neither possible nor desirable, new standards of value will have to be established that permit *all* peoples access to the means of filling the basic human needs for adequate food, shelter, clothing, employment, education, and medical care, regardless of the economic value of their productivity. Future development programs that do not face up to the problem of assuring relatively equitable use of the aid *within* a given country, are unlikely to be very successful, since the political liabilities they produce are likely to swamp any economic benefits.

Recognizing the necessity of reducing inequities within LDCs, the first question asked of any aid project should be: Will it benefit the people, or will it benefit only the government or some special-interest group in the recipient country? If the project benefits only the

[110b] Such an approach is apparently being taken in China: Vaclav Smil, Intermediate energy technology in China.

smaller groups, it should be rejected unless it can be proved that it will ultimately benefit the general population in some real and measurable way. By this standard, a steel mill might be a poor project for an LDC, for instance, even though it could provide employment for a few hundred people and would contribute to the economy. A steel mill might be justified if the country had rich deposits of iron ore that could most efficiently be processed nearby, and if export earnings seemed likely to make the investment worthwhile.

A fertilizer plant, on the other hand, would also provide employment and benefit the LDC's economy. Beyond that, the fertilizer it produced would enhance the country's ability to increase its food production and feed its population adequately. It would also allow the country to produce for itself a needed commodity that would otherwise have to be imported.

New priorities: grass-roots development. Perhaps the most urgent task for most less developed countries is to establish ecologically sensible agricultural development, with supporting facilities

for distribution, storage, and marketing of food. But, as noted in Chapter 7, agricultural development is necessarily connected with general economic improvement in rural areas: roadbuilding; production of fertilizer, farm implements, and machinery; and increased demand for food are all essential ingredients.

Even before they can be provided, many countries will have to institute meaningful reform in land ownership and tenure patterns, which largely determine the distribution of rural income and wealth. Land reform is no easy task, large landholders are usually an entrenched, conservative lot who wield considerable power. But such change *can be* accomplished, as witness the achievements of Japan (just after World War II -- and doubtless a key to Japan's successful postwar recovery), China, Taiwan, South Korea, and to some extent Mexico. [111] The last four countries are usually counted among the more successful developing nations, and their attention to land tenure and rural development has clearly been a significant factor in their success.

Development planned to help the poorest people, not aimed primarily at massive industrialization and growth of the GNP, we have called *grass-roots development*. [112]

What grass-roots development would mean in practice might, of course, vary in detail from area to area, but some needs may prove nearly universal. Ecologically sound agricultural development, rather than industrialization, should receive priority virtually everywhere, and most LDCs also have other requirements that must be met. They include medical and educational services, sanitation facilities, roads, electrification, and communications adequate to the demands of an agrarian society -- in other words, the infrastructure of modern life. In attempting to fill those needs, finding appropriate means should be the first consideration: *how to make the limited resources do the most good with the least destruction of other values* (cultural and environmental values and general well-being).

A country undergoing grass-roots development thus would move only partway along the narrow road that was taken in the past by today's overdeveloped nations, while at the same time broadening its goals and outlook. Such a nation, we hope, would learn from the mistakes of the DCs: it would create no horrors like Los Angeles; it would not base its economy on the continuing rape of the world's nonrenewable resources; it would create, in E. S. Schumacher's words, "technology with a human face." [113] Although the emphasis of grass-roots development would tend to be on agriculture, the blessings of appropriate technology in other areas would also be available, partly through indigenous manufacture and partly through cooperation and trade with ODCs and other LDCs.

Intermediate technology. One essential ingredient of grass-roots development would be deployment of what Schumacher has called *intermediate technology*. [114] This kind of technology, as he describes it, "is vastly superior to the primitive technology of bygone ages but at the same time much simpler, cheaper and freer than the supertechnology of the rich." The essence of intermediate technology is to create work places at much lower levels of capital investment than has been considered

[111] James E. Kocher, *Rural development, income distribution, and fertility decline*.

[112]This was called *semi-development* in Ehrlich and Ehrlich, *Population resources, environment*, but the image seemed wrong, and people wisely ignored the term. Live and learn.
[113]*Small is beautiful*.
[114]Ibid., p. 145.

normal in the ODCs or hertofore in the "modernized" sectors of most LDC economies. As we have mentioned (see Box 15-1), jobs are essential to helping the poor. Even if population-control measures should be successful beyond our wildest dreams, the need for millions of additional jobs every year in LDCs will persist beyond the end of the century.

The basic knowledge needed to create intermediate technologies already exists, but a large-scale effort to develop specific technologies appropriate to various situations in the poor nations has thus far been lacking. Low-cost, labor-intensive methods are urgently needed for housing and road construction, irrigation, food processing and storage, transportation, power generation, light industry, sanitation, and health-care delivery in LDCs, to name a few potential applications. Some progress is being made in developing such technologies; China has pioneered in several, including irrigation, local small-scale manufacturing, and rural health services, for instance. What has been lacking are coordinated efforts to develop such technologies, to disseminate information about them among countries, and to supply feedback on technical problems from workers in the field in LDCs to facilities in either the LDCs or the ODCs that are equipped to solve them. [115]

Energy technologies are especially critical in determining the patterns of future development in less developed countries. Policy-makers are convinced that LDCs must have access to reasonably priced energy if they are to develop at all, but they seem not to have considered the *appropriateness* of the energy technologies now being exported by industrial nations to nonindustrial ones. The energy technology being promoted most vigorously on the international market in the mid-1970s was nuclear reactors, yet one could hardly imagine a technology less well suited to the conditions in most poor countries. The economies of scale in nuclear plants make them unattractive in small sizes; malfunctions are costly and difficult to repair; and most poor countries that choose to use nuclear plants for generating energy will end up as dependent on industrial nations for their supplies of enriched uranium and for fuel-reprocessing services as they now are on OPEC nations for oil. (Less developed countries that can afford their own reprocessing plants, of course, obtain the capacity to fuel a nuclear-weapons program along with this element of independence.) [116]

How much more useful and sensible it would be to develop and export technologies that would help the nonindustrial nations to harness the flow resources -hydroelectric, plant material, sun, and wind -- which so many of them have in special abundance, which lend themselves to small, durable installations, and which would foster independence rather than dependence. Sun and wind power, in particular, have begun to show great promise for small-scale application in LDCs. [117] And they clearly could be used that way in ODCs as well.

What sorts of projects might LDCs concentrate on developing, and how does intermediate technology fit in? A prime need in many LDCs is an adequate road network; lack of roads is a

great hindrance to development efforts and may be a major factor in the urban bias of development. Roads, however, can be built without the sort of heavy machine-equipment used in ODCs. Instead, simpler techniques, resembling those used by DCs several decades ago, would probably be more efficient in poor countries and would certainly provide more employment for unskilled labor.

The same is true for extending electrification and electronic communications to poor and remote rural areas. The first goal could be to provide a single power supply, refrigeration unit, television receiver, and telephone to each village, to be used communally. This makes more sense than attempting to provide all of them at once to each home (which would be impossible anyway, at least in the foreseeable future). Once each village was supplied with the basic services, further expansion of the system could be undertaken.

---

[115] A relatively interesting, low-cost scheme for increasing scientific and technological interactions between ODCs and LDCs has been suggested by chemist Carl Djerassi, A modest proposal for increased north-south interaction among scientists. See also G. S. Hammond and W. M. Todd, *Technical assistance and foreign policy*.

[116] Reservations about these and other aspects of nuclear fission, placed in the international context, were expressed in the report of the twenty-third Pugwash conference on science and world affairs -- some 100 scientists from 29 countries -- in Finland in 1973. The relevant parts of the report are reprinted in L. Ruedisili and M. Firebaugh, eds., *Perspectives on energy*, Oxford Umversiry Press, New York, 1975, pp. 279-285. See also the section on proliferation, above.

[117] See, for instance, Abdou Moumoni, *Energy needs and prospects in the Sahelian and Sudanese zones in Africa: Prospects of solar power*; A. Makhijani and A. Poole, *Energy and agriculture in the Third World*; A. Makhijani , *Solar energy and rural development for the Third World*.

Transportation should certainly not be designed along ODC lines. Buses, whether imported or locally manufactured, are far more practical than cars in countries where only a fraction of the population can afford cars and where roads capable of accommodating cars by the million do not exist. Moreover, air pollution problems and energy constraints would render attempting to create an auto-centered transport system throughout the less developed world ill-advised, even if the other resources existed to do it. A special vehicle should be designed for LDC farmers, low-powered, economical, and sturdy. Owners of several small neighboring farms might own one communally. Alternatively, a local farmers' cooperative or the government might provide for the transport of agricultural produce to market on a pickup-anddelivery basis, and for the distribution of seed and fertilizer at appropriate times.

Farm machinery need not be highly mechanized to be efficient. Japan and Taiwan, for example, have developed very efficient agricultural systems without heavy mechanization. Economist Bruce F. Johnston has written, "simple, inexpensive farm equipment that is well suited to local manufacture in small- and medium-scale rural workshops" would be far more beneficial to the

economies of LDCs and more practical than the use of heavy machinery. [118] Not the least benefit of such a system would be its dependence upon abundant farm labor.

Irrigation systems (necessary for modern high-yield grain crops in many regions) need not be based on grand-scale, elaborate concrete dams of the sort that attract tourists in the western United States. Even where large dams are built, the projects can be labor-intensive, as some have been in India. [119] China reportedly has developed the world's largest irrigation system without use of energy- and material-consuming pumps just by using gravity to control the water flow.

Ideas for useful development projects using intermediate technology abound; the difficulty frequently lies in having them implemented. On government priority lists, modest projects that would nevertheless benefit many people, such as road-building or irrigation projects, may be outweighed by the glamor of a steel mill or a national airline. In industrial countries, small projects are usually accomplished (planned, funded, and built) locally; in LDCs the necessary resources (administrators, funds, materials, and building organizations) are generally lacking at the local level, so people must depend on the central government to supply them. A large part of the problem is the need to generate these essential resources *at the grass-roots level*: to disseminate the needed skills; to utilize the unemployed and off-season farm labor, possibly through rural cooperatives; to find the funds, either locally or outside; to mobilize the needed materials; and perhaps above all, to develop local organizational talent.

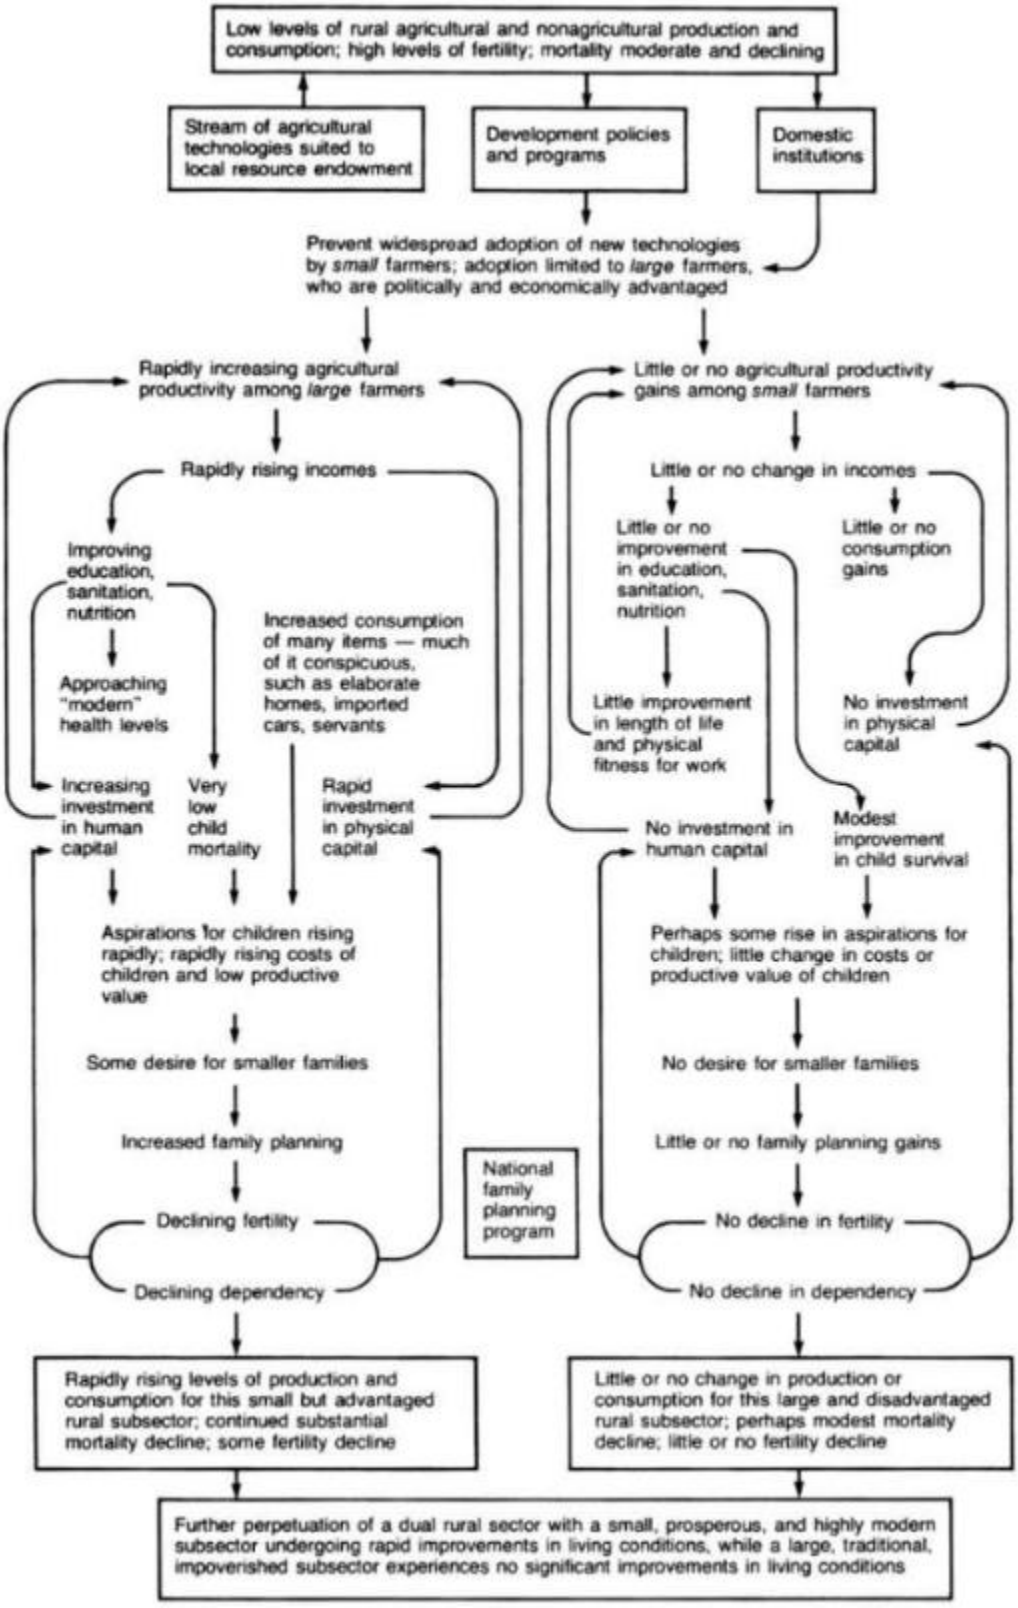
Grass-roots development and economic growth. Economist James Kocher has described how (in theory, at least) grass-roots rural development could, through various positive feedbacks, become self-reinforcing, improving the lives of the people and allowing them to make further improvements. [120] An essential part of the picture is that such development would provide motivation for family limitation, which in turn would further enable families to invest in other things (better food and housing, farm equipment, small consumer products such as sewing machines, bicycles, household items). Those goods preferably would be locally produced, thus providing employment and generating local income. Figure 15-3 shows the effects of development efforts as they have often been applied in the past: the already better-off segment of the population benefits, modernizes, and practices birth control; the impoverished majority benefits only slightly at best; and the income gap between the groups widens. Figure 15-4 shows some of the feedback effects of grass-roots development, in which generally increased well-being leads to further increases in well-being.

Kocher postulates that a necessary precondition for egalitarian rural development is the introduction of new agricultural technology. He cautions, however, that the new technology must suit the local resource endowment (physical and human). If a technology demanding a high level of mechanization, for example, is introduced in an area where a high level of underemployment already exists, the result will be the opposite of that intended -the labor will be displaced and the income gap will be widened. [121]

---

[118] Unemployment and underemployment.
[119] Myrdal, *The transfer of technology*.
[120] *Rural development*.

[121] Ibid.



Low levels of rural agricultural and nonagricultural production and consumption; high levels of fertility; mortality moderate and declining
Stream of agricultural technologies suited to local resource endowment
Development policies and programs
Domestic institutions
Prevent widespread adoption of new technologies by small farmers; adoption limited to large farmers, who are politically and economically advantaged
Rapidly increasing agricultural productivity among large farmers
Rapidly rising incomes
Improving education, sanitation, nutrition
Approaching "modern" health levels
Increased consumption of many items — much of it conspicuous, such as elaborate homes, imported cars, servants
Increasing investment in human capital
Very low child mortality
Rapid investment in physical capital
Aspirations for children rising rapidly; rapidly rising costs of children and low productive value
Some desire for smaller families
Increased family planning
Declining fertility
Declining dependency
Rapidly rising levels of production and consumption for this small but advantaged rural subsector; continued substantial mortality decline; some fertility decline
Little or no agricultural productivity gains among small farmers
Little or no change in incomes
Little or no improvement in education, sanitation, nutrition
Little or no consumption gains
Little improvement in length of life and physical fitness for work
No investment in physical capital
No investment in human capital
Modest improvement in child survival
Perhaps some rise in aspirations for children; little change in costs or productive value of children
No desire for smaller families
Little or no family planning gains
No decline in fertility
No decline in dependency
Little or no change in production or consumption for this large and disadvantaged rural subsector; perhaps modest mortality decline; little or no fertility decline
National family planning program
Further perpetuation of a dual rural sector with a small, prosperous, and highly modern subsector undergoing rapid improvements in living conditions, while a large, traditional, impoverished subsector experiences no significant improvements in living conditions

FIGURE 15-3 An example of a two-tiered rural society in which there is growth in agricultural productivity, but the benefits are mainly restricted to those who operate large farms. Widespread rural development does not take place, and there is no decline in fertility among the majority of the population. Usually, unemployment increases and generates migration to the cities. (Adapted from J. Kocher , 1973.)

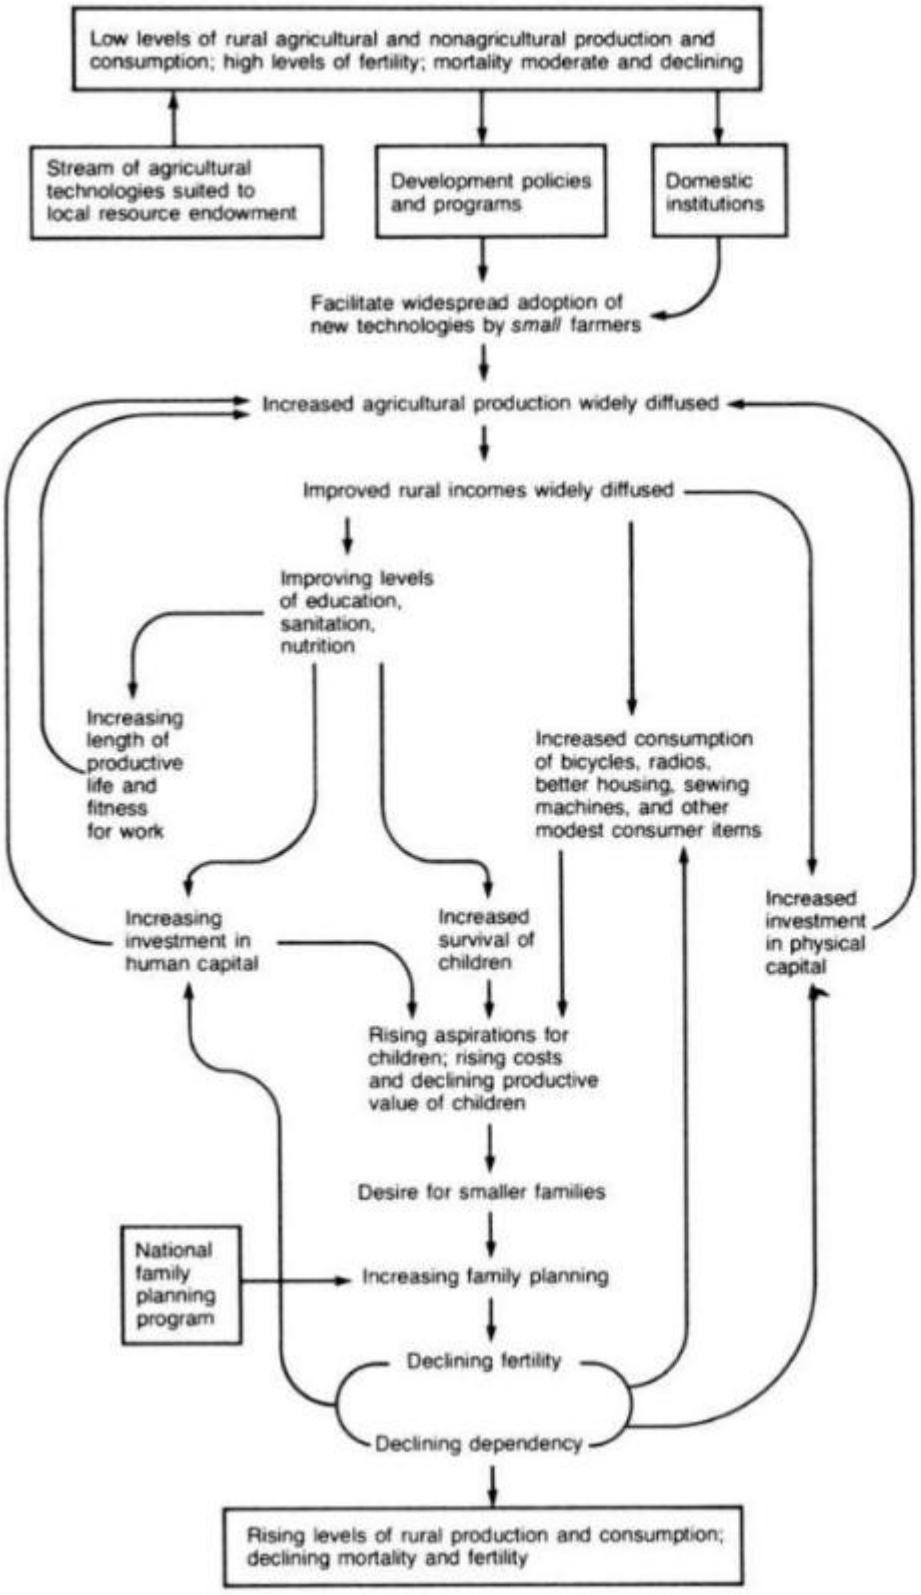


FIGURE 15-4 An example of successful grass-roots rural development, in which agricultural productivity increases among operators of both large and small farms. Consumption of food and

other products rises, as does the standard of living. Labor-intensive farming, support activities, and demand for locally produced goods combine to provide employment and to stem migration to cities. Education and other costs of raising children (along with lowered infant mortality) generate incentive for smaller families, and fertility declines. (Adapted from J. Kocher, 1973.)

Some economists and others have expressed concern that a grass-roots approach to development would result in much slower economic growth than would concentration on an industrial sector. But this does not appear to be the case. James Grant has pointed out that investment in relatively egalitarian societies (where appropriate technologies have been used, education and health care are widely available, and the income gap between the highest and lowest 20 percent of the population has *decreased* since 1950), such as Taiwan and South Korea, has produced significantly more growth in per-capita GNP than has investment in less egalitarian countries, such as Brazil, Mexico, and the Philippines. Grant concludes:

Contrary to the assumptions of the 1960s, the development record of these countries indicates that policies which enhance social equity need not deter, and may even accelerate, over-all economic growth . . . [E]quity can be more efficient than inequity and "trickle-down" in advancing growth in both rich and poor countries. [122]

There is, of course, no guarantee that grass-roots development will work -- that it will lift the poor majority out of poverty, end their chronic hunger, reduce fertility, and fulfill their hopes for a better life before the consequences of overpopulation overtake humanity. The evidence that the grass-roots approach can succeed is fragmentary and tentative at best. (Here, again, we wish dependable information existed for China, where the grass-roots approach almost in extreme form seems to be the rule. But the rest of the world must rely on what little information the Chinese government releases and on the perceptions and testimony of foreign visitors.) But, as we see it, there are no viable alternatives, and arguments in favor of grass-roots development (aside from the probability of its success) are compelling: it represents a serious, direct effort to help the world's poorest, most disadvantaged people -- especially the children, who suffer most. We see no choice but to try it.

Providing social services. The grass-roots approach to social services would assure provision of basic services to an entire population *before* the sophisticated, luxurious forms were added on for the rich minority. Unfortunately, this approach has seldom been taken.

Education is an obvious case in point. In most LDCs, educational systems mimicking those of ODCs (where universal primary education is well established) have been set up. Every LDC has at least one institution of higher learning to serve the country's elite, but most LDCs have too few primary schools. The result is that large portions of the young population are excluded from any education, because the LDC government cannot afford to extend the system to everyone. Today, over a third of the world's adults lack the skills of reading and writing; in LDCs the proportion is even higher. And, although the proportion of illiterate adults in the world declined between 1950 and 1970 (from 44 to 34 percent of the adult human population), the *absolute number* of illiterates rose (from 700 million to 800 million). [123]

One unfortunate aspect of this is that two-thirds of the illiterate adults are women. As Lester Brown, Patricia McGrath, and Bruce Stokes expressed it, while young men are being educated to participate in modern life, "Women's minds, on the other hand, are being bound as cruelly as once their feet were." [124] Yet educating women is clearly vital both for reducing fertility and for furthering the goals of development.

Moreover, education in LDCs, rather than being tailored to the needs of local cultures, often seems designed to destroy those cultures. One of the great tragedies of Latin America, for instance, is the university system that has evolved there. Latin American universities produce many attorneys, philosophers, poets, and "pure" scientists, but not the agriculturalists, ecologists, paramedics, and public-health specialists that area so desperately needs. Educational problems in India and other Asian countries are similar.

A particularly difficult question is what sort of educational system (if any) should be offered to groups that are still somewhat isolated from industrial society. We think education for Eskimos or Kalahari Bushmen should be

---

[122] James P. Grant, *Development: The end of trickle-down?*

[123] L. R. Brown, P. L. McGrath, and B. Stokes, *Twenty-two dimensions of the population problem*; Population Reference Bureau, *Literacy and world population*.

[124] Brown, McGrath, and Stokes; *Twenty-two dimensions*; see also Patricia L. McGrath, *The unfinished assignment: Equal education for women*.

designed to produce first-class Eskimos or Bushmen, not caricatures of North Americans, Englishmen, or Russians (although the option to acquire technical or academic educations should remain open to those who may desire them).

Education is particularly an area where innovations in methods and approaches are sorely needed. Mass education in traditional Western style of the rapidly growing population of children is simply beyond the means of most poor countries. It has been suggested that basic education of the masses be deferred to adulthood (or possibly adolescence), when it can be accomplished far more economically in terms of both time and money (an adult can acquire in a year the equivalent of an entire grade-school education). If effort were now concentrated on adults, especially mothers, they could then begin to teach their own children. Some educational resources might profitably be devoted to producing and distributing locally designed versions of the toys and games that prepare children in Western societies to learn in school. Satellite television broadcasting also can substitute economically for much of the educational apparatus, especially if each school or village is equipped with a receiver. Such a system has great potential for eradicating illiteracy and generally informing large segments of any population who have a common language, while requiring a minimum of trained people. A single teacher, for instance, could direct a course in basic arithmetic to the entire population of a country in a few weeks.

Medicine is another essential social service that has been inappropriately developed in many poor countries. Glittering modern hospitals can be found in most LDC capital cities, where they

provide the wealthy with the best of care. But a farmer's pregnant wife may never see a doctor before, during, or after the birth of her baby -- only a poorly trained, though experienced, midwife. Too often young doctors from less developed countries go to ODCs for advanced training in esoteric specialties. Since too few jobs exist in the home countries for their specialties, many remain in the ODCs -- despite the desperate need for competent medical care in LDCs.

Some countries are trying to change this situation. Costa Rica, Cuba, and Sri Lanka (perhaps taking a cue from China's success), for instance, have extended health services to the poor through rural clinics and with extensive use of paramedics, with the result that infant mortality rates have declined substantially. India has begun to move toward such a program also. Mexico now requires young medical doctors whose educations have been paid for by state scholarships to give a year's service each in rural clinics.

Grass-roots health care is clearly the best approach to improving the general well-being of a people. China has shown the way: start by bringing basic sanitation, hygiene, and nutrition to all the people through a network of minimally trained health-care workers backed up by paramedics, nurses, and doctors. When the basics are established, the training of health-care workers (barefoot doctors) can be progressively upgraded. This is what China has done, and it evidently works there. (See the more extensive discussion in Chapter 13.) Efforts to introduce similar programs in some other LDCs have had mixed results, however. In some places, fees are charged for services, which discourages their use. Even very low fees are a deterrent to destitute peasants. Moreover, unless birth control is included, health care for infants may not always be appreciated. [124a]

Self-sufficiency and other goals. Among development goals, that of achieving self-sufficiency is frequently mentioned. Such a goal is certainly admirable, especially if it means reaching a stage where foreign aid from ODCs is no longer needed just to keep a populace from starving and an economy from collapsing. But self-sufficiency in the sense of autonomy -- supporting a population with resources found entirely within national borders -- is in many ways undesirable and, for most LDCs, impractical.

In recent decades, the world economy has been characterized by a growing interdependence among nations. In general, despite the abuses of exploitation, this is a good thing. Perhaps its greatest value is as a deterrent to warfare, a value that may often be overlooked. But interdependence also provides people (at least potentially) with otherwise unavailable goods from distant parts of the globe. As the system has evolved,

[124a] Paul Harrison, *Basic health delivery in the Third World*.

unfortunately, there has been too much exploitive trade between ODCs and LDCs and too little of any kind between LDCs. But the system needs to be adjusted, not abolished.

Autonomy is impractical for the majority of LDCs, in part because they are small. Relative self-sufficiency may be possible for China or perhaps for India, but not for Malawi or Uruguay -- just as the United States can be more self-sufficient in this sense than the United Kingdom or the Netherlands. Not all regions can be made productive in economic terms. Some areas within Western countries today are maintained at economic expense because they supply other values -- certain parts of the United States are maintained as parks or wilderness, for instance, whereas others are heavily industrial. Similarly, some parts of the world may have to be maintained at economic expense in the future because they supply other values: natural beauty, biological or cultural diversity, survival and happiness for fellow human beings, and, in the long run, survival for everyone.

There is no reason why LDCs could not be developed differentially. Some might have considerable industry and others be limited almost entirely to agricultural development or even left partly undeveloped. Unfortunately, this option is already rapidly being foreclosed in many places, and for some areas the loss will far outweigh any long-term gains (the destruction of the Amazon basin forest is a case in point). Large industrial complexes quite reasonably could be built near rich deposits of resources: for instance, near the copper deposits in Zambia, the bauxite in Jamaica, or the oil in Nigeria, Indonesia, and the Middle East. Disparate economic entities, including concentrations of agriculture and of industry, could perhaps be loosely federated in regional economic associations similar to the European Common Market. Such associations have indeed been formed in areas such as East Africa and Central America, and they have begun to generate increased trade and specialization in products among their members.

As examples of possible alternative paths of development, Kenya and Tanzania might undergo grass-roots development while remaining primarily agricultural and recreational areas. Tanzania has been moving this way for some time; Kenya is still too much oriented toward Western-style development and has suffered as a result from problems caused by a two-tiered economy. Tanzania, Kenya, and some other African nations could supply the world with a priceless asset: a window on the past, when vast herds of large animals roamed the Earth. They could also provide one of the many living stocks of organic diversity, stocks that may prove of immeasurable value as humanity attempts to replenish the deteriorated ecosystems of the planet and seeks new foods, drugs, fibers, or other naturally-derived products. Those African nations and similar areas could serve as rest-andrehabilitation centers for people from the more frantic industrial parts of the planet -- including areas of Africa, such as Nigeria and Zambia, that are richly endowed with mineral or energy resources and might develop into highly industrial areas.

Many less developed countries could also serve as guarantors of cultural diversity, areas specifically reserved to permit peoples to maintain their traditional ways of life. One of the grim dangers facing *Homo sapiens* is the continued homogenizing of cultures, the erosion of humanity's spectacular array of cultural differences. Urbanization, mass communications, and the explosive spread of Western technology and Judeo-Christian attitudes have already irretrievably reduced this diversity. But who is to say that one world view is better than another, that a British scientist's way of structuring the world is superior to that of a Hopi Indian, that a militant Christianity is superior to a gentle Oriental religion, or that the Australian aboriginal view of kinship is inferior to that of a jet-set sophisticate?

Preserving this diversity will require nothing less than a restructuring of Western ideals and values, which have unfortunately become predominant almost wordwide. A demand must be created for the cultural resources that Australian aborigines, Eskimos, Kenyans, and Amazonian Indians can supply. Those priceless resources are in short supply, they are dwindling rapidly, and they are nonrenewable. A way must be found to permit such people access to more of the fruits of industrial societies without turning them into factory workers. This will require considerably more thought than has heretofore gone into development. How, for instance, can the benefits of modern health care be brought to, say, the

African Masai or the newly discovered Tasaday people of the Philippines without irreparably damaging their cultures? We believe ways could be found to transfer some Western technical benefits to other cultures without destroying those cultures, but it would take a major commitment on both sides.

It is encouraging to us in this context that people in less developed countries have recently become much more concerned with making their own decisions about their paths of national development. Those peoples should know best what suits their cultures and resource endowments. Unfortunately, they are still too much influenced by Western material ambitions and habits of consumption; but there are signs that this, too, is beginning to change.

The time has come for both the ODCs and the LDCs to recognize that each has a great deal of value to offer the other. Human dignity and inventiveness are certainly not the sole possession of any human group. It is possible, for instance, that LDC governments seriously interested in helping their citizens might do better to look to Peking or Havana for new ideas than to Washington, London, or Moscow. Indeed, it is quite likely that both the Americans and the Soviets could also learn from both China and Cuba. Americans might learn a lot from both countries about delivering adequate food and medical care to all their people. The Soviets might learn from the Chinese how to improve their perpetually faltering communal agriculture, and Americans might rediscover from them a sense of national purpose. The world at large has already learned something about population control from the Chinese.

That is not to say that both Cuba and China cannot in turn learn from the United States and the USSR. Both Cuba and China are much in need of the kinds of technical expertise that the ODCs have developed in so many areas, but they are certainly in the best position to judge their own needs. Fundamentally, all countries must reevaluate a long series of assumptions about such things as carrying capacity, population growth, food production, environmental deterioration, energy needs, economics, progress, equity of material distribution, and the quality of life. Perhaps the biggest step of all toward creation of genuine human community would be a recognition that what is required is not a process in which ODCs teach LDCs, communists teach capitalists (or vice versa), or scientists teach peasants, but a process of mutual learning.

INTERNATIONAL CONTROLS: THE GLOBAL COMMONS

Mutual coercion, mutually agreed upon.

-- Garret Hardin, 1968

It has been apparent for some time that the nations of this planet cannot long survive without a system of worldwide controls for dealing with the ecosphere, the world economic system, and world population growth. Such a system must above all be capable of resolving national differences. This is the basic conclusion, for instance, of Professor of international law Richard A. Falk's analysis of the situation, as exemplified by his projections of alternate future scenarios (Box 15-4).

In our opinion, one of the areas where international controls could be established most easily is over what may be called the global commons. All human beings must extract needed materials from the soil, the atmosphere, and the waters of Earth, and the hydrologic and biogeochemical cycles bind the three together into an indivisible entity. Although nations vary greatly in their mineral and fossil fuel endowments, it would clearly be wise (if not yet politically feasible) to consider *all* such supplies of nonrenewable resources as a commons also.

Idealistically, we might enter a plea here for surrendering some national sovereignty to a world government, but it is apparent that any movement in that direction will be extremely slow at best. Valuable as the United Nations has been in many respects, [125] it is clear that it will not become a supernational government in the foreseeable future. There does seem to be, however, some chance that humanity might be able to move much more rapidly than it has in the past toward international agreements on the control of the world commons. Treaties have been successfully worked out to control the

[125] See, for example, Benjamin M. Becker, *The United Nations after thirty years*.

BOX 15-4 The Falk Projections

In his 1971 book, *This endangered planet*, professor of international law Richard A. Falk of Princeton University presented two fundamental scenarios for the possible course of politics in a world threatened by ecological catastrophe. In the first scenario, he envisioned that the 1970s would see the "politics of despair." People would come to recognize that governments cannot deal with the problems of society. The gap between rich and poor nations would continue to widen, ecocatastrophes would become more common, the arms race and technological circuses would continue, while governments would
persist in their pursuit of growth of GNP. The world system would face crisis after crisis, but no organized attempts would be made to attack underlying causes. Government repression would become more commonplace, and "people will increasingly doubt whether life is worth living." By 1976 this scenario seemed frighteningly accurate.

As the first scenario proceeds, the decade of the 1980s would feature the "politics of desperation." Governments would realize their helplessness in the face of human problems, but the elites who ran them would turn more and more to repression to maintain their privileges. The suffering people of the world would become increasingly hostile toward the fortunate few living

in islands of affluence. LDCs might develop nuclear or biological warfare capability in attempts to force redistribution of resources on the ODCs. Realignments of power among ODCs and token concessions to the LDCs would be inadequate to halt this drive, so ODCs might recolonize some LDCs in order to enforce "peace" and maintain the world trade system that favored them. The United States would find itself powerless to intercede, even if it were so inclined.

"The politics of catastrophe" would take over in the 1990s. In that decade an immense disaster. ecological or thermonuclear, would overtake humanity. The reorganization (if any) of the world after the catastrophe would depend on the exact form of the disaster and who survived. The reorganization would most likely be worldoriented rather than nation-state-oriented. If, by chance, the outmoded world-order system were not irremediably damaged in the 1990s, then it certainly would be in the twenty-first century, which Falk labeled the "era of annihilation."

Falk's second scenario is more optimistic. It envisions a rapid recognition that the world system based on sovereign states cannot possibly deal effectively with the problems of the endangered planet. In this scenario, the 1970s would be the "decade of awareness," in which people in general faced squarely the nature of the emergency that engulfs human society. (By 1976, although such awareness had actually grown, it was still restricted to a miniscule portion of the world population.)

The 1980s would be the "decade of mobilization," in which awareness would be converted into action that would move people away from accepting the primacy of the sovereign state. A new worldwide political movement, based on transnational thinking, would overwhelm the conservative forces dedicated to maintaining the status quo.

The 1990s would be the "decade of transformation," in which humanity moved in the direction of stability in both population and economic systems: "A new political man will emerge from such a climate of opinion and change. The planet will be governed as a system that needs to guard against relapse and reversion, and regards the diversities within itself as a source of vitality and vigor." That decade would lead to the twentyfirst century as the "era of world harmony" - based on ecological humanism and human beings living in harmony with nature.

Obviously, we find Falk's first scenario more probable, and events of the 1970s have tended more in that direction. His second one seems wildly optimistic, especially in light of the growth-potential built into the age structure of the human population, the rapidly rising constraints on that growth, and the potential for conflict they engender. But it surely is a noble target at which to aim!

uses of outer space and Antarctica. More recently, there have been extensive negotiations on a treaty to control the use of oceans.

Law of the Sea. What has been described as "the greatest international conference ever held" [126] met in Caracas in summer 1974 to begin work on a treaty dealing with the control of the oceans. The second session of the third United Nations Conference on the Law of the Sea (UNCLOS) [127]

reached no final agreements, but in its tortuous proceedings several trends could be discerned. The emphasis was on dividing up the pie -- on how to allocate rights to exploit the oceans rather than how to protect their vital functioning in the ecosystems of Earth. The less developed nations were anxious to "augment their meager natural resources with none of the unpleasant connotations of economic aid." [128] The overdeveloped countries, on the other hand, were primarily trying to retain as much as possible of their hegemony over the seas (which they, far more than the LDCs, have the ability to exploit).

A dominant trend has been toward establishing a 200-mile economic zone, which would effectively balkanize most of the oceans' known wealth. One view is that this would lead to having humanity's common heritage decimated piecemeal as individual nations exercised dominion over all living and nonliving resources within their zones. About the only good thing that can be said about the 200-mile zone is that its establishment might lead eventually to more rational use of those resources since their individual ownership by nations would at least tend to avoid the problems involved in multilateral exploitation of a commons.

Other topics discussed in detail at the ongoing conference have been rights of passage through straits, the rights of landlocked nations to a share of oceanic resources, the establishment of an international authority for the mining of seabed minerals outside the economic zones, the responsibility of nations to control pollution originating from their shores and to protect the marine environment, and the establishment of means of settling disputes and enforcing agreements.

A third eight-week session of UNCLOS in Geneva in May 1975 produced a draft treaty, which was not voted on by the participating nations but was instead considered the basis for further negotiation. [129] The draft extended the territorial waters of all nations to 12 miles from shore, provided for a 200-mile economic zone, specified means to control polluting activities, and encouraged the transfer of technology from rich to poor nations. The most controversial provision was for an International Seabed Authority, controlled de facto by the LDCs (who would be a majority in the agency), that would regulate deep-sea mining. The United States has held out for "private initiative" to share in managing the seabed resource.

Further negotiations are scheduled for 1977. In part, their success will depend on what unilateral actions are taken by nations in the meantime. The United States, for example, has extended its jurisdiction over fisheries up to 200 miles from shore, which conforms with the draft treaty. Several other countries, including Mexico and Canada, have followed suit. But legislation being considered by Congress on deep-sea mining does not conform to the draft treaty. This places U.S. negotiators, who have tried to dissuade other nations from taking unilateral action, in an awkward position. If Congress passes such legislation, it could have a less than salubrious effect on future negotiations -- especially if American firms are permitted to begin deep-sea mining before the treaty is finally passed and ratified. On the other hand, these unilateral actions may be pushing negotiators to examine other alternatives. By 1977, Elizabeth MannBorgese was envisioning a third possibility for the Seabed Authority as "a comprehensive and flexible system of joint ventures, acceptable to states and companies under the control of the [A]uthority and for the benefit of all countries, especially the poorer ones. . . ." [129a]

[126]Elizabeth Mann Borgese, "Report from Caracas, the law of the sea", *Center Magazine*, November/ December, 1974.

[127]The first session in New York in 1973 dealt only with procedures; the first and second conferences in 1958 and 1960 had accomplished little but reveal the complexities of the problems and the diverse positions of states and blocs (see Edward Wenk, Jr., *The politics of the ocean*, chapter 6).

[128]C. R. Pinto of Sri Lanka, quoted in *Time*, July 29, 1974. It has been suggested that "The uses of international commons should be taxed for the benefit of the poorest strata of the poor countries" (Barbara Ward, *The Cocoyoc Declaration*), but there is thus far little sign that this will occur.

[129]Material in this paragraph is based primarily on Deborah Shapley, Now, a draft sea law treaty: But what comes after?

[129a]Quoted in Claiborne Pell, The most complex treaty ever negotiated in history, *World Issues*, vol II, no. 1 (February/March), 1977.

The complexity and comprehensiveness of the treaty account for the lengthiness of the negotiations. But, unfortunately, even a definitive treaty may fail to provide the kind of apparatus required to administer, conserve, and distribute the resources of the seas in a way that is equitable and that fully protects the vitally important ecosystems of the oceans, just because an exploitative view of the environment continues to dominate all such discussions.

U.N. Environment Program. The exploitative view of the environment first surfaced explicitly at the international level at the United Nations Conference on the Human Environment at Stockholm in 1972. That gathering featured platitudes from the ODCs, who are busily engaged in looting the planet and destroying its ecological systems, and demands from the LDCs that they get a piece of the action. One could only take heart that the world's nations even took the condition of the environment seriously enough to attend such a conference. That they did was a tribute to the brilliance, persuasiveness, and persistance of one man, Canadian businessman Maurice Strong, secretary general of the conference.

Strong became the first executive director of the United Nations Environment Program (UNEP), the major positive result of the Stockholm conference. UNEP was given only a small budget, and its headquarters was tucked away in Nairobi, perhaps in the hope that it would not make waves. Under Strong's leadership, it nevertheless began to serve several vital functions. For instance, it has established the Earth Watch monitoring system to serve as an international clearinghouse for environmental information. Earth Watch is explicitly designed also to help bridge the gap between scientists and technologists on one hand and political decisionmakers on the other. [130] The kinds of information to be collected include an international register of toxic chemicals, which list properties of those chemicals, their uses, their effects, and their known or inferred pathways in the environment.

UNEP's very location in Nairobi (the first such United Nations agency headquartered in an LDC) has resulted in its first major contribution -- an enormous and growing interest and concern in

poor nations about environmental problems. [131] This concern was already well established in some areas among the people [132] but had been notably absent in most LDC governments.

Under Strong's leadership a list of high-priority areas was established at UNEP: (1) human settlement, health, habitat, and well-being; (2) land, water, and desertification; (3) trade, economics, technology, and the transfer of technology; (4) oceans; (5) conservation of nature, wildlife, and genetic resources; (6) energy.

A program has been started in each area, and by early 1975 more than 200 projects had been initiated, projects that according to Strong were designed "to create a leverage to move the programme towards our priorities." [133] Unfortunately for UNEP, Maurice Strong left the agency in 1975; whether the acorn of UNEP will ever grow into the great oak of an international environmental protection organization, so desperately needed, will depend on many things -- not least of which will be the quality of its leadership.

Toward a Planetary Regime

International attempts to tackle global problems -- or at least to start a dialogue among nations -- have proliferated in recent years. Besides the UNCTAD, Law of the Sea, and Environmental conferences, the United Nations has sponsored World Population and World Food conferences (discussed earlier) in 1974, a conference on the Status of Women in 1975, the Habitat Conference of 1976 (dealing with the problems of cities), and a conference on Water Resources in 1977. A Conference on Science and Technology is scheduled for 1978, and it is expected to create a new agency for World Science and Technology Development. The agency's mission will be to facilitate the transfer of needed technologies to LDCs and to foster development of indigenous scientific and technological education and research in those countries. [134]

---

[130]Maurice Strong, *A global imperative for the environment*.
[131]Roger Lewin, *Environment in a developing world*; Jon Sigurdson, *Resources and environment in China*; Conor Reilly, *Environmental action in Zambia*.
[132]For example, see Amil Agarwal, *Ghandi's ghost saves the Himalayan trees*.
[133]Lewin, *Environment in a developing world*, p. 632.
[134]Salam, *Ideals and realities*.

Superficially, it usually appears that such conferences do little more than highlight the political differences between rich and poor countries, but in fact they can lead to constructive action on the problems discussed. Because of the diversity of interests and viewpoints of individual nations, and because of the inequities of the world economy, it seems to take an unconscionably long time to reach a consensus on dealing with each problem. But an important step often is to obtain agreement that *a problem exists*, first of all, and, second, that international action is appropriate and necessary. Each of the conferences named has been the culmination of this process; but what counts for the future is whether agreement can be reached on solutions to the problems and whether controls can be established before it is too late.

Regulation of one vital global commons has not yet been seriously discussed -- that commons is the atmosphere. Even more than the resources of the oceans, the atmosphere is shared by all human beings -- and other organisms as well. It is crucial to preserve the atmosphere's quality and the stability of global climate. [135] But that these are now threatened and should be protected by international agreement is only beginning to be recognized in a few quarters.

Should a Law of the Sea be successfully established, it could serve as a model for a future Law of the Atmosphere to regulate the use of airspace, to monitor climate change, and to control atmospheric pollution. Perhaps those agencies, combined with UNEP and the United Nations population agencies, might eventually be developed into a Planetary Regime -- sort of an international superagency for population, resources, and environment. Such a comprehensive Planetary Regime could control the development, administration, conservation, and distribution of *all* natural resources, renewable or nonrenewable, at least insofar as international implications exist. Thus, the Regime could have the power to control pollution not only in the atmosphere and the oceans, but also in such freshwater bodies as rivers and lakes that cross international boundaries or that discharge into the oceans. The Regime might also be a logical central agency for regulating all international trade, perhaps including assistance from DCs to LDCs, and including all food on the international market.

The Planetary Regime might be given responsibility for determining the optimum population for the world and for each region and for arbitrating various countries' shares within their regional limits. Control of population size might remain the responsibility of each government, but the Regime should have some power to enforce the agreed limits. As with the Law of the Sea and other international agreements, all agreements for regulating population sizes, resource development, and pollution should be subject to revision and modification in accordance with changing conditions.

The Planetary Regime might have the advantage over earlier proposed world government schemes in not being primarily political in its emphasis -- even though politics would inevitably be a part of all discussions, implicitly or explicitly. Since most of the areas the Regime would control are not now being regulated or controlled by nations or anyone else, establishment of the Regime would involve far less surrendering of national power. Nevertheless, it might function powerfully to suppress international conflict simply because the interrelated global resource-environment structure would not permit such an outdated luxury.

What the Human Community Can Do

Humanity has reached a critical point in its history. Either the fissioning of societies into two distinct groups -- rich and poor -- will proceed, leading inevitably to conflict and possibly to economic collapse of some regions, at least; or serious efforts will be made to bring the two groups closer together. With regard to the latter course, as we have discussed at some length, there are plenty of ideas on how to go about it. The main obstacles are, as usual, social, political, and economic. Too few people in ODCs are convinced of the absolute necessity of reducing their consumption of material and environmental resources -- of de-development. Too few people in all countries appreciate the environmental and resource constraints within which society must

operate. And too many people with power oppose changing the present course because, for the time being, they are profiting from the status quo. And it may not be possible

[135]S. H. Schneider and L. E. Mesirow, *The genesis strategy*.

to change the course of human society until those powerful people are fully convinced that their benefits will vanish unless they do.Assuming that the formidable obstacles can nevertheless be overcome and the two separate "worlds" started on the appropriate paths -- the rich world begins to de-develop, and the poor world undertakes grass-roots development -- full cooperation between the two groups will be required to make it work. Biologist Charles Birch, paraphrasing Garrett Hardin, described such cooperation as "mutual concern mutually agreed upon." [136] The LDCs cannot succeed without substantial assistance from ODCs, and the ODCs will continue to need commodities and resources from LDCs to maintain their industrial structures, even if those structures are made vastly more efficient and are partially transferred to LDCs. The most crucial decades are those just ahead, in which there must be a transition to a size-controlled (eventually declining) population, an internationally regulated Planetary Regime for the global commons, and something resembling the "dynamic equilibrium economy" espoused by Herman Daly and Emile Benoit.Certain guiding principles for national behavior have been proposed by many individuals as being essential to the establishment of a genuine world community in which such cooperative measures could be carried out. As outlined by United States Assistant Secretary of State John Richardson, Jr., a consensus is emerging:

1. Governments ought to promote the general welfare of those they govern, not merely enlarge their own and the nation's power;
2. Starvation anywhere is unacceptable;
3. Torture by governments anywhere is unacceptable;
4. The use of nuclear and biological weapons is unacceptable; and
5. Political, cultural, and ideological diversity -within some limits -- ought to be tolerated. [138]

Managing the transition to what some people have called a sustainable world [139] without a major catastrophe of some kind (war, mass famine, pandemic, ecological disaster, or economic collapse), will require far more than good luck. It will require careful planning and hedging against such unpredictable eventualities: Schneider and Mesirow's "Genesis strategy." (The Genesis strategy is based on the biblical story in which Joseph warned the pharaoh of Egypt that seven fat years would be followed by seven lean years, and he advised the pharaoh to store up grain during the fat years to tide the population over when famine came.) Thus, high priorities must be given by the international community to building up food reserves, to preventing and repairing major environmental damage, to protecting the ocean and atmospheric commons, to preventing high casualties from natural disasters (earthquakes, volcanic explosions, hurricanes, and such), to protecting populations against disease, to avoiding conflict between nations, and to that essential concomitant of all of these -- population control. There is movement toward these precautionary measures, but so far the movement is dishearteningly slow.

Humanity cannot afford to muddle through the rest of the twentieth century; the risks are too great, and the stakes are too high. This may be the last opportunity to choose our own and our

descendants' destiny. Failing to choose or making the wrong choices may lead to catastrophe. But it must never be forgotten that the right choices could lead to a much better world.

Howe, James W., ed. 1975. *The U.S. and world development: Agenda for action 1975*. Praeger, New York. A timely and useful compendium on development problems. Some useful tables in the back.

-----and J. W. Sewell. 1975. Triage and other challenges to helping the poor countries develop. In *The U.S. and world development: Agenda for action 1975*, J. W. Howe, ed., pp. 55-71. Claims, "the evidence of human progress has been lost from sight altogether."

Huisken, Ronald. 1975. The consumption of raw materials for military purposes. *Ambio*, vol. 4, pp. 229-233. Useful data on this colossal waste of Earth's resources.

Ignotus, Miles. 1975. *Seizing Arab oil*. Harpers, March, pp. 54-62. This article, written under a pseudonym by a "professor and defense consultant with intimate links to high level U.S. policy-makers" was widely viewed as an administration trial balloon. See also Robert W. Tucker, "Oil: The issue of American intervention".

Illich, Ivan. 1969. Outwitting the "developed" countries. *New York Review of Books*, November 6. On some unconventional development strategies. Illich's recommendations are in the same spirit as E. F. Schumacher's in Small is beautiful.

-----. 1970. *Celebration of awareness*. Doubleday, Garden City, N.Y. Brilliant book by one of today's most imaginative thinkers. See especially Chapter 10, Sexual Power and Political Potency, in which Illich discusses the population situation in Latin America.

International Atomic Energy Agency (IAEA). 1976. *A short history of nonproliferation*. IAEA, Vienna. Very useful summary of the origins of the Nonproliferation Treaty and its implementation. Includes full text of the treaty and list of signers and nonsigners as of February 1976.

Jacoby, Neil H. 1969. The progress of peoples. *Center Occasional Papers*, vol. 2, no. 4. Center for the Study of Democratic Institutions, Santa Barbara, Calif. An interesting discussion of the problems of development.

Jahoda, J. C., and D. L. O'Hearn. 1975. "The reluctant Amazon basin". *Environment*, October. Summarizes problems of development.

Jalée, Pierre. 1968. *The pillage of the Third World*. Modern Reader, New York. A leftist view of neocolonialism.

Jarrett, Henry, ed. 1966. *Environmental quality in a growing economy*. Johns Hopkins Press, Baltimore. An interesting collection. See especially the article by Boulding, The economics of the coming Spaceship Earth.

Jasani, Bhupendra M. 1975. "Environmental modifications: New weapons of war?" *Ambio*, vol. 4, pp. 191-198. A review of the possibilities.

Jensen, C. E.; D. W. Brown; and J. A. Mirabito. 1975. *Earthwatch, Science*, vol. 190, pp. 432-438 (October 31). An ambitious (and acronym-loaded) discussion of what a global environmental assessment program operated by UNEP could be like.

Johnson, B. 1976. "International environmental conventions". *Ambio*, vol. 5, no. 2, pp. 55-65. An excellent overview.

Johnston, B. F. 1972. Unemployment and underemployment. In *Are our descendents doomed?* H. Brown and E. Hutchings, Jr., eds. Viking, New York. Recommends intermediate technology for LDC farms.

Kahn, Herman. 1960. *On thermonuclear war*. Princeton University Press, N.J. This book brought much unfair personal criticism of Kahn. It is the subject of devastating professional analysis by Philip Green in *Deadly logic*.

-----. 1962. *Thinking about the unthinkable*. Horizon, New York. An able reply to the personal attacks made on Kahn after On thermonuclear war was published.

-----. 1965. *On escalation*. Penguin, Baltimore. The most recent work by the best known of the deterrence theorists.

Keeny, Spurgeon M., Jr., Chairman. 1977. Nuclear power issues and choices. *Report of the Nuclear Energy Policy Study Group of the Ford Foundation*. Ballinger, Cambridge, Mass. A thoughtful and largely evenhanded review of the technical, economic, environmental, and political issues surrounding nuclear power, with heavy emphasis on proliferation. Recommends deferral of plutonium recycle and commercialization of the liquid metal fast breeder reactor in the U.S., with continued reliance on light water reactors.

Koohane, R. O., and Van Doom Ooms. 1975. The multinational firm and international regulation. *International Organization*, vol. 29, pp. 169-209.

Keyfitz, Nathan. 1976. "World resources and the world middle class". *Scientific American* July, pp. 28-35. An important article on the prospects of improving the well-being of the world's poor majority.

Kissinger, Henry. 1975. "Speech before United Nations General Assembly", September 2. Reprinted in the *New York Times*, September 2, p. 20. This was the speech in which the United States pledged to help LDCs through increased aid and improved trade agreements.

Klare, Michael T. 1976. "The political economy of arms sales". *Bulletin of the Atomic Scientists*. November, pp. 11-18. The U.S. is still the world's leading arms peddler, and the trade is flourishing.

Kratzer, Myron B. 1975. "International cooperation in nuclear energy and nonproliferation". *Current Policy, The Department of State*, vol. 7, November. He does not believe proliferation is inevitable; he is overly optimistic about such things as the IAEA safeguards.

Ledogar, Robert J. 1975. *Hungry for profits: U.S. food and drug multinationals in Latin America*, IDOC/North America, New York. Claims that in the Latin American milieu of minimal regulation and self-medication United States drug companies have often made their profits at the expense of the health of the local people. Says that the activities of the food companies, especially the substitution of cash crops for subsistence crops, has often resulted in lower quality diets for the hungriest people.

Lewin, Roger. 1975. "Environment in a developing world". *New Scientist*, March 13, pp. 632-633. A brief description of the first years of UNEP.

-----. 1975. "International attack on insect pests". *New Scientist*, April 17, pp. 124-125. Describes functioning of International Centre of Insect Physiology and Ecology (ICIPE) in Nairobi.

Lessey, Julian. 1976. "Taxes for conservation". *New Scientist*, October 7, p. 30. A proposal to tax nonrenewable resources imported by DCs from LDCS, to encourage conservation and benefit LDC economies.

Lewis, Paul. 1974. "Getting even". *New York Times Magazine*, December 15. Interesting discussion of the OPEC revolution. Points out that by 1974 Arab "development aid is already up to the target set by the United Nations-something which cannot be said for the rest of the industrial world and particularly for the United States, which is not only the world's richest nation but also its meanest."

Lipton, Michael. 1975. "Urban bias and food policy in poor countries". *Food Policy*, vol. 1, no. 1, pp. 41-51. How the poorest people are left out of the food economy in LDCs.

Lockwood, Lee. 1967. "Castro's Cuba, Cuba's Fidel". Random House, New York. Contains an interview in which Castro describes his approach to Cuban grass-roots development.

Lovins, Amory, and John H. Price. 1975. *Non-nuclear futures: The case for an ethical energy strategy*, Lippincott, Philadelphia. Eloquent, thoughtful exploration of alternative energy futures for the world.

Low, H. C., and J. W. Howe. 1975. Focus on the Fourth World. In *U.S. and world development: Agenda for action 1975*, J. W. Howe, ed. Problems of the poorest group of LDCs.

McGrath, Patricia L. 1976. The unfinished assignment: Equal education for women. *Worldwatch paper* 7, Worldwatch Institute, Washington, D.C.

Makhijani, A. 1976. "Solar energy and rural development for the Third World". *Bulletin of the Atomic Scientists*, June. Pleads for decisionmakers not to emulate industrial nations but to spread small solar technologies to benefit poor. A good example of grass-roots development.

----- and A. Poole. 1975. *Energy and agriculture in the Third World* Ballinger, Cambridge, Mass. On appropriate energy technology for LDCs. Excellent.

Mazrui, Ali A., 1975. The new interdependence: from hierarchy to symmetry. In *The U.S. and world development: Agenda for action 1975*, J. W. Howe, ed., pp. 118-134. A rather optimistic view.

Melko, Matthew. 1975. "Peace: A subject worth studying". *Bulletin of the Atomic Scientists*, April, pp. 31-34. Gives a list of peaceful societies and suggests investigating why they are peaceful.

Melman, Seymour. 1962. Disarmament, its politics and economics. *American Academy of Arts and Sciences*, Boston, Mass.

-----. 1970. *Pentagon capitalism: The political economy of war*. McGraw-Hill, New York. See especially Chapter 7 for a summary of myths about the military establishment. Melman sees it as independent of real United States needs, defense or economic.

Mesarovic, M., and E. Pestel. 1974. *Mankind at the turning point*. A second report from the Club of Rome that criticizes The limits to growth, Meadows et al., but hardly presents a more encouraging view of the "problematique."

Moumoni, Abdou. 1973. "Energy needs and prospects in the Sahelian and Sudanese zones in Africa: Prospects of solar power". *Ambio*, vol. 2, no. 6, pp. 203-213. On sensible kinds of energy development for LDCs.

Muller, Mike. 1974. "Aid, corruption and waste". *New Scientist*, November 7, pp. 398-401. Points out the key role in preventing famine played by preventing hoarding by maintaining confidence in the market system. Claims this has been a major achievement of United Nations Disaster Relief Organization.

Murdoch, W. W., and A. Oaten. 1975. "Population and food: Metaphors and the reality". *BioScience*, vol. 25, September, pp. 561-567. A critique of Hardin's lifeboat ethics.

Myrdal, Alva. 1974. "The international control of disarmament". *Scientific American*, October. Source of information on arms-control agreements.

Myrdal, Gunnar. 1968. *Asian drama*. 3 vols. Pantheon, New York. A monument on politics, economics, planning, and population in Asia. Comprehensive and rather depressing.

-----. 1974. "The transfer of technology to underdeveloped countries". *Scientific American*, September, pp. 173-182. On the existing barriers to the transfer of technology and how they might be overcome.

National Academy of Sciences (NAS). 1975. *Long-term worldwide effects of multiple nuclear-weapons detonations*. NAS, Washington, D.C. Although some of the individual sections are competent, the overall conclusions are not. The letter of transmittal by Philip Handler was especially unfortunate.

New Internationalist. 1976. The world is your shopping basket: trade special, who sells what, where, and who makes the money. Vol. 38, April. A key issue of an important journal. See especially the UNCTAD IV supplement in this issue.

Newland, Kathleen. 1975. Women in politics: A global review. Worldwatch Institute, Washington, D.C., *Worldwatch paper* 3. Data on voting and literacy rates by sex, women in national legislative bodies, and so forth.

Nitze, Paul H. 1976. "Assuring strategic stability in an era of détente". *Foreign Affairs*, vol. 54, no. 2 (January), pp. 207-232. A knowledgeable hawk argues that SALT agreements may be leading to instability of the nuclear deterrence system.

O'Brien, Tom. 1975. "Marrying Malthus and Marx". *Environmental Action*, August 30, pp. 3-11. A splendid synthesis of Marxist and Malthusian ideas in the context of the present human predicament.

Ohlin, Goran. 1967. *Population control and economic development*. Organization for Economic Co-Operation and Development, Paris. An important early analysis on the interactions of growth and development.

Paddock, W., and P. Paddock. 1967. *Famine, 1975!* Little, Brown, Boston. The classic application of the triage principle to food aid for hungry nations.

Patel, I. G. 1976. "What the developing countries really want". *Atlas World Press Review*, February, pp. 22-23. Food and shelter are not their only aspirations.

Pearson, Lester B. 1969. *Partners in development*. Praeger, New York. Report to the World Bank by the Commission on International Development.

Peccei, Aurelio. 1969. *The chasm ahead*. Macmillan, London. A distinguished Italian industrialist and member of the Club of Rome examines the human predicament and reaches conclusions startlingly close to those of many ecologists.

Pincus, John A., ed. 1968. *Reshaping the world economy*. Prentice-Hall, Englewood Cliffs, N.J. Especially useful source on world trade problems.

Pirages, Dennis C. ed. 1977. *The sustainable society: Social and political implications*. Praeger, New York. A collection of articles with technological, economic, and political viewpoints pertinent to this chapter.

-----, and Paul R. Ehrlich. 1974. *Ark II: Social responce to environmental imperatives*. W. H. Freeman and Company, San Francisco. A detailed examination of many of the subjects of this chapter.

Plate, Thomas G. 1971. *Understanding doomsday*. Simon & Schuster, New York. A gold mine of information on the arms race.

Platt, John. 1969. "What we must do". *Science*, vol. 166, pp. 1115-1121 (November 28). A classification of our multiplicity of crises and suggestions on how we might meet them.

Population Reference Bureau. 1975. "Literacy and world population". *Population Bulletin*, vol. 30, no. 2. Illiteracy and the need for population-control information go hand in hand.

Pugwash Conference. 1973. Twenty-third conference report. *Congressional Record*, Senate, vol. 119, pp. S18727-S8730, October 8. The conference's working group on energy expressed reservations about the proliferation of nuclear plants and fuel-reprocessing facilities in LDCs.

Rand, C. T. 1975. *Making democracy safe for oil*. Little, Brown, Boston. Describes the role of the oil industry in the Arab oil embargo.

Rathjens, George W. 1969. *The future of the strategic arms race: Options for the 1970's*. Carnegie Endowment for International Peace. Old but good.

Reilly, Conor. 1975. "Environmental action in Zambia". *Environment*, October, pp. 31-35. Zambia is staffing to face up to the problems of rapid industrialization and exploitation of natural resources.

Renshaw, E. F. 1976. *The end of progress: Adjusting to a no-growth economy*. Duxbury Press, North Scituate, Mass. Superb overview of the global predicament and the prospects for evasive action in the form of a transition to a sustainable state.

Ribicoff, Abraham A. 1976. A market-sharing approach to the world nuclear sales problem. *Foreign Affairs*, vol. 54, pp. 763-787. Proposes a variety of national and international measures to stop the export of nuclear fuel reprocessing facilities, with the aim of slowing proliferation of nuclear weapon.

Robinson, J. P. Perry. 1975. "The special case of chemical and biological weapom". *Bulletin of the Atomic Scientists*, May, pp. 17-23. Expresses concern that these might evolve into being thought of as conventional weapons.

Rose, William M. 1975. "Submarine vs. anti-submarine: The billion dollar merry-go-round". *Bulletin of the Atomic Scientists*, April, pp. 27-30. Discusses the Trident SLBM system-another military boondoggle.

Rothschild, Emma. 1976. "Food politics". *Foreign Affairs*, January, pp. 285-307. On the role of food in international economics and politics.

Roy, Robin. 1976. "Myths about technological change". *Nero Scientists*, May 6, pp. 281-282. Brief overview of various theories about relationships of society to galloping technology.

Sakharov, Andrei D. 1968. "Progress, coexitence and intellectual freedom". Norton, New York. Heroic statement by the brilliant physicist called the father of the Russian H-bomb.

Salam, Abdus. 1976. "Ideals and realities". *Bulletin of the Atomic Scientists*, vol. 32, no. 7, pp. 9-15. A Pakistani scientist examines the rich-poor confrontation.

Sampson, Anthony. 1975. *The seven sisters: The great oil companies and the world they shaped*. Viking, New York. A "biography" of the organizations that play such a crucial role in the energy situation, providing insights into the international control of petroleum.

Sanders, Sol. 1969. *A sense of Asia*. Scribner's, New York.

Schelling, Thomas C. 1968. *The strategy of conflict*. Oxford University Press, Oxford. Well worth reading. Schelling is one of the brightest of the deterrence theorists.

Schneider, William Jr. 1975. "Agricultural exports as an instruments of diplomacy". *Food Policy*, vol. 1, no. 1. Concludes that U.S ability to export food (or withhold it) could be a useful tool in economic warfare.

Sewell, J. W. ed. 1977. *The United States and world development agenda 1977*. Praeger, N.Y. The Overseas Development Council's fifth annual assessment of U.S. relations with the LDCs. Very useful discussions of food, population, technology transfer, arms sales, income distribution, and other important topics, backed up with extensive tabulations of recent statistical data.

Shapley, Deborah. 1975. "Now, a draft sea law treaty: But what comes after?" *Science*, vol. 188, p. 918 (May 30).

Sherwood, Martin J. 1975. *A world destroyed*. Knopf, New York. A brilliant overview of the origins of United States atomic policy, much of it based on recently declassified information. Emphasizes early attempts to make A-bombs a United States-UK monopoly.

Sigurdson, Jon. 1975. Resources and environment in China. *Arabio*, vol. 4, pp. 112-119. Environmental considerations enter into Chinese development plans, which include decentralized industrialization, delayed urbanization, and a concern for fundamental human needs. A "friendly" overview.

Singer, J. D., and M. Small. 1972. *The wages of war, 1816-1965: A statistical handbook*. Wiley, New York. A compendium of data on wars: periodicity, seasonal factors, who was involved (how disposed nations and regions are to war), severity, battle deaths, and so forth.

Singh, Kushwant. 1975. "The international basket case". *New York Times Magazine*, January 26. Describes conditions in Bangladesh.

Sivard, Ruth L. 1975. "Let them eat bullets!" *Bulletin of the Atomic Scientists*, April, pp. 6-10. Discusses the impact of the world's spending $30 million per hour on armed forces and armaments.

Smil, Vaclav. 1977. "Intermediate energy technology in China". *Bulletin of the Atomic Scientists*. February, pp. 25-31. Interesting view of how China is rapping energy resources on a small-scale, local basis for rural industry and household use. Among sources being used are coal, hydropower, biogas, and solar heat.

Sommer, John G. 1975. "U.S. voluntary aid to the Third World: What is its future?" Overseas Development Council, development paper 20, Washington, D.C. An interesting summary of the pitfalls of various aid programs.

Springell, Peter. 1975. "Some observations on the Australian environmental scene". *Ecologist*, February, pp. 42-47. See especially the section on the trade unions.

Sprout, H., and M. Sprout. 1971. *Toward a politics of the planet Earth*. Van Nostrand Reinhold, New York. Political scientists take a comprehensive look at the human dilemma. Chapter 11 is especially interesting.

Stauffer, T. 1974. "Oil money and world money: Conflict or confluence". *Science*, vol. 184, pp. 321-325 (April 19). On recycling petrodollars.

Stavrianos, L. S. 1976. *The promise of the coming dark age*. W. H. Freeman and Company, San Francisco. A weirdly optimistic tour de force by an author who could use further education in ecology.

Stockholm International Peace Research Institute (SIPRI). 1976. Why arms control fails: The myth of "deterrence" lulls world opinion. *Atlas World Press Review*, February, pp. 11-13. Contains data on overkill and weapons systems and discusses the failure to disarm.

Stolnitz, George J. 1974. Population and labor force in less developed regions: Some main facts, theory, and research needs. In *Employment in developing nations*, E. O. Edwards, ed. Columbia University Press, New York. pp. 235-245. A good overview.

Stone, Christopher D., and Jack McNamara. 1976. "How to take on OPEC". *New York Times Magazine*, December 12, pp. 38ff. Describes a plan by which U.S. government might break the cartel.

Thayer, George. 1969. *The war business: The international trade in armaments*. Avon, New York. A detailed description of the conventional arms trade.

Time. 1975. "Poor vs. rich: A new global conflict". December 22. A popular review defining the first-through-fifth-world terminology.

Tinker, Jon. 1974. "Java: Birth control battlefield". *New Scientist*, February 21. Describes how corruption permeates the social and political system in one LDC.

----- . 1974. "Is technology neocolonist?" *New Scientist*, May 9, pp. 302-305. A fascinating review of Indonesian environmental problems as seen by Mocktar Lubis, environmentalist and editor of a Jakarta newspaper.

Tsipis, Kosta. 1975. "The long range cruise missile". *Bulletin of the Atomic Scientists*, April, pp. 15-26. The technology and implications of this frightening new development are discussed.

Tucker, Robert W. 1975. "Oil: The issue of American intervention". *Commentary*, January, pp. 21-31. Possibly another trial balloon. Despairs of success in recycling petrodollars and the possibility of the Arabs' acting reasonably.

United Nations. Annual. *Statistical yearbook*. Statistical Office of the United Nations, New York. A gold mine of information on population, manufacturing, agriculture, trade, consumption, and so forth.

United States Arms Control and Disarmament Agency (ACDH). 1975. *SALT lexicon*. Rev. ACDH, Washington, D.C. A useful guide for translating the jargon-riddled literature on nuclear war. Sample: "Crisis Stability: A strategic force relationship in which neither side has any incentive to initiate the use of strategic nuclear forces in a crisis situation."

Van der H. Schalie 1974. "Aswan dam revisited". *Environment*, vol. 16, no. 9. Describes increase of schistosomiasis.

Vermeer, Donald E., 1976. "Food, farming and the future: The role of traditional agriculture in developing areas of the world". *Social Science Quarterly*, vol. 57, pp. 383-396. An important paper indicating the crucial role that traditional agriculture must play in solving the world food problem.

Voevodsky, John. 1969. "Quantitative behavior of warring nations". *Journal of Psychology*, vol. 72, pp. 269-292. Shows that there is considerable orderliness in numbers of troops engaged, battle deaths, and other statistics of modern wars.

Ward, Barbara (chairperson). 1975. "The Cocoyoc declaration". *Bulletin of the Atomic Scientists*, March, pp. 6-10. This is an excerpt of the statement produced by an international meeting of social and natural scientists at Cocoyoc, Mexico, in October 1974, sponsored jointly by UNCTAD and UNEP. The declaration calls for a new international economic order.

Wenk, Edward Jr. 1972. *The politics of the ocean*. University of Washington Press, Seattle. Becoming out of date but still a useful source on the complexities of controlling the oceanic commons.

Williams, E. J., and F. J. Wright. 1975. *Latin American politics: A developmental approach*. Mayfield, Palo Alto, Calif. An excellent survey of the political actors in the region and the historic and economic dimensions of their stage.

Wright, Quinsy. 1965. *A study of war*. 2d ed. University of Chicago Press. A huge volume, dealing primarily with wars prior to 1941 (first edition). Wright has a four-factor theory of the origins of war, these being technology, law, social organization, and distribution of opinions about basic values. A rich source of information. See especially the appended commentary on war since 1942.

York, Herbert F., ed. 1973. *Arms control: Readings from Scientific American*. W. H. Freeman and Company, San Francisco. A wide-ranging collection.

-----. 1976 *The advisors: Teller, Oppenheimer, and the superbomb*. W. H. Freeman, San Francisco. An insightful history of the decisions leading to the development of the U.S. and Soviet hydrogen bombs, by an insider on the U.S. side. Must reading for those interested in the psychology of the arms race.

Zeckhauser, Richard. 1973. *The risks of growth. Daedalus, fall*, pp. 103-178. States, "recycling is not the solution for oil, because the alternate technology of nuclear power generation is cheaper," (p. 117). This paper helps demonstrate how ignorance of the physical world keeps many economists from coming to grips with the international situation.

CHAPTER 16
Summary

The future is purchased by the present.

-- Samuel Johnson, *The rambler*

At the end of Chapter I we contrasted two possible views of the present human condition and the prospects for the future. Obviously, the spectrum of opinion on this most important of issues is continuous and not confined to two well-defined camps. Nevertheless, it is helpful, after struggling with the enormous body of principles, data, estimates, and arguments considered in the intervening chapters, to try to summarize some of the essential points by referring again to two distinct camps. We call them cornucopians and neo-Malthusians.

CORNUCOPIANS VERSUS NEO-MALTHUSIANS

Cornucopians are often preoccupied with the apparent theoretical capacity of Earth to supply a large (but fixed) population with basic raw materials over long spans of time. They refer to the vast stores of minerals available at low concentration in seawater and in the first few miles of Earth's crust, and they argue that cheap and abundant energy from fission breeder reactors or controlled ther-

monuclear fusion will make those dilute mineral resources economically accessible (as well as permitting large-scale desalting of seawater with which to make the deserts bloom with food crops). Even ardent cornucopians do not postulate continued population growth beyond a few more doublings, however, for that many people could not be sustained under any assumptions.The neo-Malthusians reject the hypothetical steadystate scenario as largely irrelevant. They focus on rates -the dynamic character of the problem -- arguing that (1) technology does not provide adequately for the *present* world population, (2) technology and resources cannot be mobilized (or paid for) quickly enough to provide adequately for the much larger population to which humanity seems imminently committed, and (3) serious environmental errors are being made and will continue to be made in the hasty attempts to mobilize technology and resources quickly enough. In short, the neo-Malthusians perceive not an "equilibrium problem" (can a world be imagined in which 20 billion people, 5 times the present population, could be supported?) but rather what a mathematician would call an "initial-value problem" (how can we get from here to there, and especially with such a bad start?). Some observers on both sides have asked reflectively whether anyone would *like* a world with 10 or 20 billion people in it, but that is another matter.When cornucopians do come to grips with the dynamic aspects of the problems, their argument generally relies on the timely and smooth operation of the price mechanism to bring about substitution and technological innovation as required. They view continued economic growth as the path by which the poor will acquire the means to participate in the price mechanism.The neo-Malthusian view fears "stickiness" in the price mechanism, dramatic price rises for raw materials that will prevent the poor from achieving prosperity, and nonlinear mechanisms (such as diminishing returns, thresholds, synergisms) that will cause moderate increases in population and resource demand to generate disproportionate economic, social, and environmental costs. According to this position, it is likely that human demands and impact at some point in the future will exceed a (possibly dynamic) limit as it stands *at that time*, leading to a large increase in the human death rate or in the incidence of poverty. The neo-Malthusian view proposes conscious accommodation to the perceived limits to material growth via population limitation and redistribution of wealth, in order to prevent the "overshoot" phenomenon.On these points we find ourselves firmly in the neo-Malthusian camp. We hold this view not because we believe the world to be running out of materials in an absolute sense, but rather because the barriers to continued material growth, in the form of problems of economics, logistics, management, and environmental impact, are so formidable.

DEFECTS IN THE CORNUCOPIAN VISION

Of the defects in the cornucopian argument, the gravest are these:

The presumption that advanced technology will make energy very cheap;

The presumption that abundant, cheap energy -- if available -- would prove to be a sufficient condition for abundance of all kinds;

The serious underestimation of the degree of environmental degradation that would be generated by the proposed cornucopian technologies;

The even more serious underestimation of the impact on human well-being that major environmental disruption portends.

First, there is little reason to believe that energy will get cheaper. The advanced energy technologies with the greatest potential in terms of abundance -- solar energy, controlled fusion, and fission breeder reactors -- are all characterized by raw fuel that is free, or nearly so; but the

high capital costs likely to be associated with those technologies will lead to high overall energy costs despite free fuel.

Cheap energy, even if it should miraculously materialize, is not enough. Food, shelter, clothing, education, and opportunity for the billions will certainly require energy, but they will also require other raw materials, social organization and cooperation, and much help from

the already beleaguered processes of the biosphere. The processes by which energy can be "converted" into the other needed raw materials are often difficult, usually environmentally disruptive, and almost always expensive. Social stresses arising from competition for energy and materials make organization and cooperation more difficult, not easier. And the side effects of the escalating flows of energy and Materials through civilization are diminishing the capacity of the biosphere to support human activities at a time when the need for such support is expanding.

The widespread tendency to underestimate the future environmental damages of the energy and materials technologies has two facets -- an overconfidence in technology's capacity to "clean up" the environment, and a narrow view of environmental disruption that includes direct assaults on health via emission of pollutants but not the systematic damage to life-supporting ecosystems via, for example, habitat destruction, overexploitation of plant and animal species, erosion, and alteration of the chemical environment in soil and surface water.

With respect to technology's capacity to clean up, it is true, of course, that the environmental impact of many of today's energy and materials technologies can and should be dramatically reduced. For each proposed technical fix, however, it is important to ask: How fast can it be implemented? How much of the hazard will it abate? What will society do for an encore after those gains have been erased by further growth? How much will it cost, and who will pay? Will it produce new negative impacts in exchange for the ones abated?

For some environmental impacts of energy and materials technologies, no fix is in sight: Carbon dioxide, for example, is produced by combustion of fossil fuels in quantities too large to contain, and it may already be influencing climate. Particles less than 1 micron in diameter (emitted by combustion of fossil fuels and to a lesser extent by mining operations and agriculture) mostly escape available controls; unfortunately, the sizes smaller than 1 micron are precisely the most serious in terms of both human health and the disruption of climate. The human factor may make it impossible to design foolproof safeguards against nuclear-fission disaster. Finally, heat is the ultimate pollutant. In the unlikely event that nothing else stops the growth of energy use first, heat will stop it by generating major climatic disruption. This outcome is predictable from the laws of thermodynamics; it can be postponed somewhat by clever reliance on solar energy, but it cannot be averted.

The gravest threat to human well-being arising from the environmental impact of energy and materials technology is probably not direct poisoning by the emissions, but rather the loss of natural services now provided by biogeochemical processes. Contrary to popular belief, such natural services cannot be replaced by technology now or in the foreseeable future. Not only do

we not know how to do it, but if we did, we couldn't afford it. What is alarming is that civilization, while unable to replace the natural services upon which its survival depends, has become a great enough disruptive force to undermine them. The available evidence is insufficient to prove conclusively that disaster is upon us, but it indicates we are playing in a league where environmental balances on regional and global scales hinge on human actions.

ALTERNATIVE APPROACHES TO TECHNOLOGY AND WELL-BEING

This summary so far, consistent with the material in the foregoing chapters, has presented a pessimistic view of the human predicament and the prospects that current trends will improve it. We believe that a realistic prognosis would now include continuing worldwide inflation; further widening of the prosperity gap between rich and poor; increased incidence of famine and quite possibly other environmentally-related increases in death rates; heightened social unrest characterized by strikes, riots, and terrorism; more frequent international confrontations over resources; a rising level of international tension aggravated by all these factors, with a probability of nuclear conflict that increases not only in proportion to this level of tension but also in some (perhaps nonlinear) relation with the growing number of possessors of nuclear weapons. What, then, can we advocate?

It is clear, first of all, that no combination of policies and technologies can significantly ameliorate the predicament unless it overcomes the nontechnological roots of the problem: population growth, competitive nationalism, racism, the maldistribution of wealth and opportunity, the illusion that economic throughput and material well-being are directly proportional, and the hubris that supposes civilizations to be self-supporting without help from natural ecosystems. The highest priority must therefore be given to measures that directly attack these driving forces.

The cornerstone of a rational program should be a great reduction in the growth of throughput of energy and materials in the rich countries. Such a reduction would permit, in principle, an *acceleration* of the application of energy and materials to meet the genuine needs of the poor countries, within a context of *slackening global growth*. In this way, the gap in prosperity between rich and poor could begin to close -- a prospect that supporters of rapid overall growth have often held out to the poor but never delivered. At the same time, the slower growth in the rate at which energy and materials are mobilized worldwide, and the even slower growth in the rich countries, where certain environmental impacts of energy and materials technologies are now most severe, would significantly reduce the grave environmental risks that accompany continuation of recent trends.

The success of such a scheme, of course, depends strongly on the success of programs to limit the growth of populations. Only at lowered rates of population growth can the relatively high increase in the use of energy and materials per person that is needed in the poor countries be achieved within an economically and environmentally sustainable rate of global growth. In the rich countries, the effect of multiplying even small population increments by the very high levels

of resource use and environmental impact per person already prevailing there makes it essential to approach a zero rate of population growth as soon as possible.

Another essential ingredient of the approach we advocate is a massive, coordinated worldwide campaign of research, development, and implementation aimed at increasing the well-being actually delivered for each unit of energy and raw-materials throughput, while decreasing the amount of adverse environmental impact per unit of throughput. This proposal should be recognized as a prescription not for less technology but for better technology -- more frugal, better focused on the most compelling needs, more compatible with the fabric of the physical and social environments.

The potential of increased technological efficiency notwithstanding, the pursuit of efficient technologies must be tempered by two concerns. The first is that even the most efficient technology must be applied and expanded cautiously, lest the environmental impact of its throughput disrupt environmental services or social relationships of greater importance than the services the technology provides. The second concern is to avoid the pitfall of trading away too much diversity in the singleminded pursuit of efficiency. One must generally pay something extra in throughput for diversity. In this sense, diversity is inefficient, but many natural ecosystems seem to demonstrate that diversity is good insurance against uncertainty about the future, and civilization would probably do well to learn from the example. Just how much of this insurance civilization should buy and what it will cost are questions that need further study.

Within these constraints, the potential for favorably altering the ratio of service to throughput by a major directed effort means that prosperity in the poor countries can be increased at a rate greater than the rate at which resource use is growing. And it means that, even in rich countries where a drastic slowing of growth in energy use is called for, ingenuity can reduce the impacts on the economy and on the prospects for increases in actual well-being. This possibility, together with increased awareness in the rich countries that their own well-being is imperiled by the social, economic, and environmental consequences of continuing present trends, provide the only real basis for believing that the technological changes and rich-poor reallocations envisioned here can actually take place.

Obviously, the best approaches to increasing the ratio of service to throughput will not be identical for all regions. It seems clear from the difficulties enumerated in Chapter 15 that new technology for the developing regions must be tailored to specific local conditions rather than transferred wholesale from industrial nations. Rather than centralization, technical complexity, standardization, and interdependence, the characteristics of

new technologies for developing regions should be, insofar as possible, dispersal, simplicity, diversity, and independence. Durability and reliability, which often go hand in hand with simplicity, are also essential. It is evident that the technologies of industrial nations, as well, should in many instances evolve away from complexity and centralization, and in all instances they should move away from reliance on a standard of perfection in manufacture, maintenance, and operation that is simply not attainable in practice.

Industrial nations, rich as they may seem to be, must also recognize that they are not rich enough to do what must be done while wasting resources on entirely frivolous economic fiascoes. Supersonic transports, overproduction of subsonic air buses, a proliferation of unfillable luxury hotels and vacation condominiums -- all are economic blunders that will cause some well-deserved bankruptcies but, unfortunately, only after desperately needed technical and economic resources have been wasted.

Military expenditures are in a category by themselves. No one can afford them, the poor even less than the rich. But most countries make them -- to a total of almost $300 billion worth per year worldwide. This cannot be considered merely a waste, inasmuch as the expenditures profoundly threaten human well-being through what is bought even more than through what is not bought. The most powerful single lever at the disposal of industrial nations for narrowing the prosperity gap is to shut off all sales and gifts of military hardware to the poor countries uniformly, replacing them with offerings of technologies selected for their abilities to contribute to genuine increases in well-being. Naturally, the gesture will be a hollow one if the industrial nations do not at the same time divert their own expenditures on weaponry to productive purposes.

EPILOGUE

We are regularly informed in all solemnity that the sorts of drastic changes proposed here are economically, politically, and socially impractical or unrealistic. No one has yet devised a plausible scheme, for example, to see that reductions in throughputs of resources in the rich countries (if they could actually be achieved) are translated into increased availability of resources for rational development in the poor countries. Little real progress has been made on global disarmament by the superpowers, and extensive proliferation of nuclear weapons is widely (if quietly) held to be inevitable. The seriousness of population growth continues to be widely underestimated or misperceived by scholars and governments alike. We believe it is past time for the social-science community to devote its full attention to the removal of these sociopolitical obstacles to societal survival, just as the physical-science and engineering communities must devote theirs to the transformation of technology. For the alternative of proceeding along the present course is not only even less practical economically, politically, and socially than the demanding changes that are required, it is also impractical *physically*. The real question, for those concerned about realistic solutions, is whether scholars and decision-makers of all varieties can devise ways to bring human behavior into harmony with physical reality in time.

APPENDIX 1
World Demography

Most of the figures for Table A1-1 are from the 1976 *World Population Data Sheet* of the Population Reference Bureau, Inc., Washington D.C. The exception is per-capita energy consumption figures, which are from the Environmental Fund's *Population Estimates*, 1974 (see below).

Population estimates for many countries undoubtedly contain a large margin of error. In many cases census data are extremely unreliable; in others undetected changes in birth or death rates since the latest census may introduce considerable error into extrapolations. And, of course, in some instances the figures may represent faulty extrapolations from incorrect census data.

The approximate character of available world demographic data was underlined by the appearance since 1974 of population data sheets produced by the Environmental Fund, Washington, D.C., showing strikingly different figures for many countries (including the United States) from those of the U.N. or the U.S. Bureau of the Census. Their explanations for the discrepancies are not implausible and may in many cases be correct. For example, the Environmental Fund includes an estimate of illegal immigrants in its U.S. figures, whereas the Census Bureau and most other organizations do not include them.

On the whole, we believe the figures we are presenting here are the best estimates available. Most of them, of course, should be considered to represent rough magnitudes. A difference of a point or two in birth rates between two countries may have no significance whatever. The most accurate census data come from the DCs; those of many LDCs are extremely suspect. The per-capita gross national product figures should be used with special caution; since population figures and total GNP are both only approximate at best, per-capita GNP figures, a ratio of the two, are especially liable to error. The major features of the current world demographic picture are clear in these data, but in using them their limitations should always be kept in mind.

Table A1-2 shows the population projections of demographer Tomas Frejka in detail (see Chapter 5), demonstrating population momentum.

[a]Included are all United Nations members and all geopolitical entities with populations larger than 200,000.

[b]Based on the U.S. Bureau of Census estimate for mid-1974 or on the most recent official country or United Nati
estimate was for mid-1974) and updated to mid-1976.

[c]For the developed countries, with complete or nearly complete registration of births and deaths, nearly all the ra
all the developing countries, with incomplete registration, the rates refer to the 1970-1975 period and we taken fi
estimates
and projections as assessed in 1973. These figures should be considered as rough approximations only.

[d]Based on population changes during part or all of the period since 1970. For most countries these rates are the s
the
time periods to which the two rates pertain are different and because the birth and death rates as well as the popu
countries are

Region or country [a]	Population estimate, mi-1976 (million) [b]	Birth rate [c]	Death rate [c]	Rate of population growth (annual, percent) [d]	Number of years to double population [e]	Population projection to 2000 (millions) [f]	Infant mortality rate [g]	Population under 15 years (percent)	Median ex age (years)

generally rough approximations only, small differences between the two rates should not be considered as precis
emigration.
Larger differences between them do indicate that migration has been a factor in population change.

[e]Based on the rate of population growth shown and assuming no change in the rate.

[f]Except for the United States, based on the application of the percentage increase in the population 1975-2000 im
projections to the population total as estimated for mid-1975. For the United States, the figure shown is the Serie
Census.

[g]Rates pertain to 1973 or 1974 or latest available estimates, generally obtained from the sources cited above.

[h]The percentage of the total population living in areas defined as urban by each country.

[i]Data from *World Bank atlas*, 1975.

[j]In kilograms of coal equivalent (derived from U.N. data).

[k]The United Nations does not show figures for Taiwan. These figures were estimated separately. The population
year
2000 at the same rate as that of the People's Republic of China.

Source: Population Reference Bureau, *1976 World population data sheet*; per-capita energy consumption from T
estimates 1974.

*Paths were chosen to represent reasonable estimates of when an NRR of 1.0 might be reached. For countries with NRRs in 1970 of 1.75 or more, the rapid and slow paths were used; countries with 1970 NRRs below 1.75 were expected to grow along the lines of the immediate and rapid paths.

APPENDIX 2
Food and Nutrition

Despite the emphasis on the need for a balanced diet that has been a part of school curricula and general public information in the United States since the 1920s and 1930s, some Americans are still convinced that a typical Asian can live happily and healthily on one bowl of rice per day. The truth is that an Asian's nutritional requirements are just the same as those of an American, although the total amounts an Asian may need of some nutrients may be less, because of the Asian's smaller size (itself doubtless the result of poorer nutrition during the years of growth). The Asian, however, meets his or her nutritional needs through a quite different assortment of foods from those an American would choose.

The traditional diets of various peoples of the world differ tremendously, from the East African Masai diet of berries, grain, vegetables, milk, blood from cattle, and some sheep or goat meat, to the Polynesian diet of coconut, fish, breadfruit, taro, tropical fruits, and occasional pork or poultry. American and European diets -- once based on relatively few foods, such as beef, mutton, poultry, dairy products, eggs, wheat and other cereals, potatoes (more recently), pulses, vegetables, and fruits -- have grown in the past generation to include a fantastic array of foods from all parts of the world. Nevertheless, the relatively limited traditional diets of most of the people in less developed countries, where undernutrition and malnutrition are today very widespread, could be basically adequate to meet their needs.

The existing nutritional deficiencies result mainly from insufficient supplies of some or all of those foods. Lack of sufficient food may be a result of being too poor to buy it or ignorance of the best choices, or both. (The inexcusably poor diets of many Americans are more often due to ignorance of nutrition or to indifference than to poverty.) Table A2-1 shows available food energy and protein supplies per capita in the world averaged over 1969 through 1971. Diets of lowerincome groups in less developed countries are often seriously deficient in kilocalories (and, accordingly, in other nutrients as well). Surveys in several LDCs have shown very clearly the discrepancies in food intake per person between highest and lowest income families (Tables A2-2 and A2-3).

As rapid population growth in LDCs has strained efforts to maintain food supplies, demand for imported food has increased dramatically, especially since 1972. This trend is shown in Table A2-4, comparing the quantities of grain exported (traded between countries) with total production and consumption. The bulk of exported grain goes to developed countries, but the share exported to LDCs has been rising rapidly in recent years. Table A2-5 shows United Nation's projections of expected increases in worldwide demand for various kinds of food between 1970 and 1985.

THE ESSENTIAL NUTRIENTS

Some knowledge of basic nutrition is important, both for understanding the world food situation and for optimizing one's own health through better nourishment. Some forty-five compounds and elements found in foods are considered essential nutrients, necessary for life and health in human beings. These nutrients fall into five general categories: *carbohydrates, fats, proteins, vitamins*, and *minerals*. Each nutrient can be found in a wide variety of foods, although no one food contains all of them. Each performs some particular function or functions within the body, providing energy, building and repairing tissue, or maintaining the physiological processes of life. [1]

Carbohydrates and Fats

Energy for the life processes and for activity is obtained through "burning" food in the process known as metabolism. Usually this energy is provided by carbohydrates and fats, although if those elements are undersupplied, proteins may be utilized to make up the deficit. The potential energy from food is measured in kilocalories. One kilocalorie (kcal) is the amount of energy (in the form of heat) required to raise the temperature of 1 kilogram of water 1° C.

Carbohydrates are sugars and starches. They are both made of the same elements -- carbon, hydrogen, and oxygen. In digestion, starch (which is a structurally more complicated molecule) is broken down to simple sugars. These sugars may then be metabolized at once or stored for future needs.

Sugars are found most abundantly in fruits, and to a smaller extent in vegetables, milk, and milk products.

---

[1]For a detailed summary of the nutrient contents of a wide variety of foods, see The Department of Agriculture handbook 8, *Composition of foods*, Washington, D.C., 1963, also published as *Handbook of the nutritional contents of foods*, Dover Publications, New York, 1975. Bernice K. Watt and Annabel L. Merrill eds.

Refined sugars, which are used in cooking, baking, and preserving, come from sugar cane or sugar beets. Starches are found in cereals and vegetables, especially pulses and root vegetables such as potatoes and yams.

Fats are present in both plant and animal foods, as well as eggs and dairy products. Besides being a source of energy, whether used directly or stored as a reserve, fats are important structural constituents of cell membranes. They also provide the sheaths that surround nerves, help to support internal organs, and assist in the utilization of fat-soluble vitamins.

When insufficient supplies of carbohydrates and fats are eaten, the stored reserves are consumed and weight is lost. There is usually an accompanying curtailment of physical activity. If the weight loss continues until the reserves are gone, the individual starves. Food-energy starvation is often hard to distinguish from other deficiencies. Even if enough protein is provided in the diet to meet protein needs, it is instead metabolized for its caloric value, so protein deficiency results. Vitamins and minerals are also likely to be undersupplied when intake of carbohydrates and fats is too low.

A diet deficient in fats is likely to produce irritability and possibly deficiencies in the fat-soluble vitamins.

Needs for food energy are related to body size, age, and level of activity. Children and pregnant or nursing mothers need proportionately more kilocalories relative to their body weights than other adults, to support growth. A man engaged in extremely heavy work may need nearly twice as much food energy as a man with a sedentary job. Table A2-6 shows the National Academy of

Sciences-National Research Council recommended dietary allowances for most nutrients, including kilocalories.

Proteins

Proteins are the structural materials of life, including human life. They also serve in many other roles, as enzymes (biological catalysts) and as oxygen transport compounds (hemoglobin). Most parts of the body -- muscles, bones, skin, even hair and blood -- are made up largely of proteins. Whereas there are millions of different proteins, all of them are built from about twenty *amino acids*. The differences are in the arrangements and proportions of the amino acids. These subunits, in turn, are composed primarily of carbon, nitrogen, oxygen, and hydrogen. When eaten, the complicated protein molecules are broken down in digestion into their constituent amino acids, which are then reassembled in the body to meet protein needs. Eight of the amino acids are essential in our diets; the others can be synthesized from simple precursors.

Proteins are essential for growth and development, for tissue maintenance and repair, and for healing and recovery from disease. They also play a part in regulating the metabolism of sugar. To support growth, infants and children need higher proportions of protein relative to their body weights than adults. So, for the same reason, do pregnant and lactating (nursing) women. Physical activity does not affect protein needs, although severe illness or injury does increase those needs temporarily.

Proteins are found in virtually all foods, but in enormously differing quantities and qualities. Completeprotein foods -- those that contain all of the essential amino acids -- are primarily animal foods: meat, fish, poultry, eggs, and dairy products. Nuts and pulses also provide substantial amounts of protein, and cereals have moderate amounts, but all of these are of lower quality. This means that the essential amino acids in these foods do not occur in ideal proportions for meeting nutritional needs. Protein of the highest quality (except for mother's milk) is found in eggs, and that of the next best quality is found in cow's milk.

Foods containing lower-quality protein can, however, be combined to make meals with high-quality protein. One of the best is to combine a pulse with a cereal. Thus, many traditional mixtures from various cuisines -- Mexican tortillas and beans; Chinese mixtures of rice, beans, and nuts; New England's baked beans and brown bread -- actually are high-quality protein meals.

Small amounts of animal protein such as milk or meat can also greatly enhance the quality of vegetable proteins. Here again, the combination is superior in quality to each component taken separately. It should be emphasized, though, that the separate components must be consumed *at the same time* in order to work; having rice for breakfast and beans for lunch will not do the job. [2]

[2]For a detailed description of protein combinations plus recipes, see Frances Moore Lappé's *Diet for a small planet*, 2d ed., Ballantine, New York, 1975.

TABLE A2-6 Recommended Daily Dietary Allowances

								Fat-soluble vitamins						*Water-solu*

Lactating						+500	+20	6,000	400	15	80	600	+4	+0.5

Note: The allowances are intended to provide for individual variations among most normal persons as they live i
States under usual environmental
stresses. Diets should be based on a variety of common foods in order to provide other nutrients for which huma
been less well defined. See text
for more detailed discussion of allowances and of nutrients not tabulated. IU = international units.

Source: Food and Nutrition Board, National Academy of Sciences-National Research Council, 1973.

A diet deficient in protein results in a lack of energy, stamina, and resistance to disease. In children the result is retarded growth and development. If the deficiency is severe and continues over a long period of time, even if the child survives to adulthood, he or she may never fully recover (see Chapter 7).

Vitamins

Vitamins are essential nutrients needed in minute amounts compared with carbohydrates, fats, and proteins. They fill a variety of needs in the regulation of life processes. The lack of any of the thirteen or more essential vitamins leads to problems of cellular metabolism, which may lead to a serious deficiency disease and ultimately to death. Many vitamins are depleted or destroyed

by exposure to light, air, heat, or alkaline conditions. They are therefore often lost from food through improper storage or cooking methods.

Vitamins fall into two general classes: fat-soluble (vitamins A, D, E, and K) and water-soluble (B complex and C). The fat-soluble vitamins can be absorbed only in the presence of bile salts, which are brought into the digestive system by fat in the diet.

Vitamin A exists in vegetables and fruits in a precursor form known as *carotene*, which is converted in the liver to Vitamin A. It is found as Vitamin A most abundantly in liver, eggs, and dairy foods. It is needed for normal vision, healthy skin, gums, and soft tissues, and for resistance to respiratory illnesses. Vitamin A is a precursor of *retinene*, which together with a protein makes up visual purple, the photosensitive substance of the retina.

A lack of Vitamin A first shows up in night blindness, skin problems, and susceptibility to colds. When it is more extreme, the visual and skin problems intensify, and blindness may result (*xeraphthalmia*). Blindness from Vitamin A deficiency is a major health problem in some LDCs.

TABLE A2-6 (Continued)

The Vitamin B complex consists of at least eight vitamins, which were originally thought to be only one when first discovered. These vitamins are necessary for efficient metabolism. Although they perform different functions, they seem to act somewhat synergistically, and they often occur together in foods. The richest sources of the entire complex are liver, whole grains, yeast, and unpolished rice. Deficiencies involving several B vitamins simultaneously are fairly common. The lack of one also may impair the action of the others.

Thiamine (Vitamin B_1), besides having an important role in carbohydrate metabolism, is necessary in regulating growth and in maintaining the health and functions of the circulatory, digestive, and nervous systems. Its absence leads to the disease known as beriberi, whose symptoms are lack of energy, nervous and emotional disorders, and digestive and circulatory disturbances.

Beriberi often accompanies a high-carbohydrate diet, usually one based on polished rice. The thiamine in rice is in or just under the outer skin of the grain, which is removed in milling. Where rice is hand-pounded, undermilled, or parboiled (soaked and partly cooked) before milling, at least some of the thiamine is preserved. But polished rice is preferred in many countries for its keeping qualities and because the product of milling (the polishings or husks) may be used as livestock feed. Infantile beriberi, an acute form of the disease caused by deficiency in the mother during pregnancy, strikes breastfed infants and soon leads to death unless it is treated promptly.

Beriberi was for a time widespread in Southeast Asia and the Philippines. This was partly because of the introduction of modern community rice mills, which eliminated the need for hand-pounding, formerly done at home. Pregnant and nursing women in those areas by tradition

were restricted to very limited diets, which further curtailed their intake of thiamine as well as other vitamins and protein. Specific nutritional programs have

recently reduced the incidence of beriberi in Southeast Asia.

Riboflavin (Vitamin B_2) is also involved in carbohydrate metabolism, functioning as a coenzyme. Deficiency leads to problems with eyes, the central nervous system, and the skin (*ariboflavinosis*). This deficiency frequently appears together with Vitamin A deficiency. Riboflavin is found in the usual B-vitamin foods, plus milk and eggs.

Pyridoxine (Vitamin B_6) also functions as a coenzyme involved in protein and fat metabolism. It is needed for healthy skin, nerves, and muscles.

Vitamin B_{12}, unlike the other B vitamins, is not found in vegetable sources; it is obtained mainly from milk and liver. It is used therapeutically for treatment of pernicious anemia and probably normally prevents its occurrence. (Strict vegetarians, who avoid even milk and eggs, run a risk of developing pernicious anemia.)

Niacin (nicotinic acid) participates in a wide variety of metabolic processes as part of the NAD

⇌ NADP electron-transfer system. It is essential for normal function of the nervous system, soft

tissues, skin, and liver. The symptoms of deficiency include mental disorders, skin problems, and swollen gums and tongue. The severe deficiency disease *pellagra* is characterized by the "three Ds" -- diarrhea, dermatosis, dementia. This disease often is found among people whose staple food is corn. In Latin America it somehow seems to be avoided through the practice of soaking corn in limewater before grinding it. Pellagra was a serious problem among poor families in the southeastern United States before World War II.

Choline is essential for normal functioning of the liver, the kidneys, and several glands, as well as for fat metabolism.

Pantothenic acid functions as a component of *coenzyme A*, involved in carbohydrate, fat, and protein metabolism. It is needed for growth, for the health of the skin, the digestive tract, and the adrenal gland.

Folic acid is involved in the regulation of red blood cells and the function of the liver and glands. Deficiency may lead to liver and digestive disturbances.

Biotin is essential to cellular metabolism and functions, among other places, in the Krebs cycle. Deficiency produces an anemia, skin and heart disorders, sleeplessness, and muscular pain.

Other B vitamins are *para-aminobenzoic acid* (PABA) and *inositol*. PABA is an intermediate in folic acid synthesis, and inositol is involved in the metabolism of fats.

Vitamin C (ascorbic acid) is essential for healthy skin, gums, and blood vessels. It is also built into cell walls and is necessary for their continuing strength. Vitamin C also is an important factor in resistance to stress and infection. This vitamin is widely found in fruits, peppers, leafy green vegetables, and potatoes, the richest sources being peppers and citrus fruits. It is relatively unstable, being quickly destroyed by heat, and cannot be stored in the body for more than a few days.

Symptoms of Vitamin-C deficiency include bleeding gums, a tendency for small blood vessels to break and hemorrhage, and low resistance to infection. Extreme deficiency is the familiar disease of sailors and explorers, *scurvy*. Scurvy still appears occasionally in arid countries during drought or famine. Mild cases have been found among the urban poor, especially the elderly, even in developed countries.

There is growing evidence that official recommended daily allowances of Vitamin C are much too low, being barely enough to prevent the appearance of severe deficiency symptoms. Everyone interested in nutrition should read Linus Pauling's provocative *Vitamin C, the common cold, and the flu*. [3] The book is controversial, but we and many of our colleagues have increased our Vitamin C intake to hundreds or thousands of milligrams per day. Read this book and decide for yourself.

Vitamin D is sometimes known as the sunshine vitamin. The precursor *ergosterol*, which is obtained from green plants, is changed to Vitamin D in the skin when it is exposed to sunlight. In developed countries today, most commercially sold milk is enriched with Vitamin D through irradiation. The only satisfactory source of converted Vitamin D, if sunshine and irradiated milk are unavailable, is fish liver oils. It is quite likely that the thick blanket of smog hanging over American cities interfers with the manufacture of Vitamin D in urban populations, which has implications for adults who do not drink fortified milk.

Vitamin D is intimately involved in the absorption and utilization of calcium and phosphorus (see below), and

[3] W. H. Freeman and Co., San Francisco, 1976.

consequently in the growth and maintenance of the bone structure. *Rickets* is a disease of children who lack Vitamin D and/or calcium and phosphorus. In these children the growth and development of the bones is disturbed and retarded. The children may be permanently stunted and have more or less malformed bone structure. The corresponding disease in adults is *osteomalacia*, in which the bones become brittle and are easily broken. This occurs when calcium is drawn from the bones to meet daily needs and is not sufficiently replaced in the diet over a long period of time.

Vitamin E seems to be involved in reproductive functions; lack of it may lead to repeated miscarriage. It is obtained from nuts and vegetable oils, particularly wheatgerm oil.

Vitamin K is essential to normal blood-clotting activity. This vitamin is ordinarily manufactured by intestinal bacteria and is also found in green leaves, fat, and egg yolks. The intestinal supply may be cut off temporarily following an antibiotic regime, especially one that is orally administered.

Minerals

Seventeen of the essential nutrients are minerals. Many of them are required only in minute amounts.

Bones and teeth are composed primarily of *calcium* and *phosphorus*. Calcium also plays a part in the regulation of nerves and muscles and is necessary for healthy skin and for blood-clotting. The best source of calcium is milk, followed by yellow cheeses. It can also be obtained from the bones of fish and other animals and from green vegetables, shellfish, and lime, which is sometimes used in the preparation of food. Hard water used for drinking or in cooking also contributes calcium.

Phosphorus is closely involved with calcium in bonebuilding and nerve and muscle regulation. It is also important in sugar metabolism and the utilization of vitamins, and it is critically involved in transfers of energy in living systems. Phosphorous is abundant in dairy foods, poultry, eggs, and meat and occurs in moderate amounts in most vegetables. Deficiency is therefore relatively uncommon.

Iron is an essential component of hemoglobin, the protein in red blood cells that carries oxygen to the cells of the body. *Iron-deficiency anemia* is the commonest kind of anemia. Its symptoms include lack of energy and stamina. It is more common among women, whose iron needs are higher due to blood loss in menstruation and the demands of pregnancy. Anemic women are susceptible to stillbirth and miscarriage and are likely to produce anemic children. Iron is most abundant in liver, other organ meats, eggs, molasses, oysters, and apricots. Smaller amounts are found in meat and green vegetables.

Sulfur is necessary for the building of some proteins in the body and must be ingested in amino acids. It is found in many high-protein foods, both plant and animal.

Sodium chloride -- ordinary table salt -- is essential to life, although toxic in too large doses. It occurs naturally in seafoods, meat, and a few fruits and vegetables. It is also found in processed foods such as cheese, bread, and canned foods. Vegetarians may have difficulty getting enough salt, otherwise deficiency is unlikely except where there is danger of heat prostration.

Potassium is a widely available mineral found in meat, fruits, and vegetables. Together with sodium, potassium helps to regulate the body's fluid balance. Too much of either can cause a deficiency of the other. Potassium also is essential for metabolism of sugar in muscle cells. It is needed most during periods of rapid growth.

Iodine is an essential component of thyroid hormones that regulate growth, development, and metabolic activities. It is found in seafood and in crops grown in iodine-rich soil. Its lack results in *goiter*, characterized by a swelling of the thyroid gland in the neck. In extreme forms of this disease, cretinism or deaf-mutism may be produced in children. Before World War II goiter was relatively common in the interior of the United States, where seafood was unavailable and the soils lack iodine. Since then iodized salt has been available, use of which prevents goiter.

Zinc is a component of insulin and therefore involved in the body's utilization of carbohydrates and protein. It is found in pulses, organ meats, and green vegetables. Recent research indicates that it may be more important than was believed earlier and that contemporary fertilizing methods may result in crops being deficient in zinc.

Magnesium is necessary for the utilization of both

calcium and Vitamin C. It is found in a wide variety of foods.

Manganese is necessary for lactation and some other glandular functions. It is obtained from a variety of nuts and vegetables.

Some other trace elements that are necessary for health are: *chromium, cobalt, copper, molybdenum*, and *selenium*. Deficiencies in these minerals have rarely, if ever, been seen.

It is quite possible that other essential nutrients exist that have not yet been isolated. The importance of trace elements cannot be overemphasized. Because they are often required in such minute amounts, and perhaps because there seems to be considerable individual variation in requirements, there is some tendency to overlook them. The wisest course to follow if one cares about maintaining health is to eat as wide a variety of foods as possible, preferably from different geographical areas, choosing from among each of the major food groups every day: protein foods (meat, poultry, fish, eggs, beans, or nuts), dairy foods, cereals or tubers, vegetables, and fruits. To ensure the least loss of fragile vitamins, one should choose fresh food in preference to processed foods and cook it minimally.

APPENDIX 3
Pesticides

THE FIRE ANT PROGRAM: AN ECOLOGICAL CASE STUDY

The red fire ant (*Soknopsis invicta*) is a nasty, but nottoo-serious pest in the southeastern United States. Its nests form mounds that interfere with the working of fields. Its stings may cause severe illness or death in sensitive people, but it is a considerably smaller menace in this regard than are bees and wasps. The ant is best described as a major nuisance. After limited and inadequate research on the biology of the fire ant, the USDA in 1957 came up with the astonishing idea of carrying out a massive aerial spray campaign, covering several states, against

the ant. Along with other biologists, including those most familiar with the fire ant, one of us (P.R.E.) protested the planned program, pointing out, among other things, that the fire ant would be one of the *last* things seriously affected by a broadcast spray program. A quote from a letter he wrote concerning the problem to Ezra Taft Benson, then Secretary of Agriculture, follows:

To any trained biologist a scorched-earth policy involving the treatment of 20 million acres with a highly potent poison such as dieldrin should be considered as a last ditch stand, one resorted to only after all of the possible alternatives have been investigated. In addition such a dangerous program should not even be considered unless the pest involved is an extremely serious threat to *life* and property.

Is the Department of Agriculture aware that there are other consequences of such a program aside from the immediate death of vast numbers of animals? Are they aware that even poisoning the soil in a carefully planned strip system is bound to upset the ecological balance in the area? We are all too ignorant of the possible sequelae of such a program. Has it been pointed out that an adaptable and widespread organism such as the Fire Ant is one of the least likely of the insects in the treated area to be exterminated? It is also highly likely that, considering its large population size, the Fire Ant will have the reserve of genetic variability to permit the survival of resistant strains.

I would strongly recommend that the program be suspended: 1) until the biology of the ant can be thoroughly investigated with a view toward biological control, baiting, or some other control method superior to broadcast poisoning, and 2) until trained ecologists can do the field studies necessary to give a reasonable evaluation of the chances of success, and the concomitant damage to the human population, wildlife, and the biotic community in general of any contemplated control program.

I hope that the United States will learn from the disastrous Canadian Spruce Budworm program and hesitate before carrying out a program whose consequences may be a biological calamity.

This reply came from C. F. Curl, then Acting Director of the USDA Plant Pest Control Division. Note the emphasis on eradication in this excerpt:

Surveys do indicate that the imported fire ant infests approximately 20,000,000 acres in our southern states. This does not mean, however, that the eradication program is embarked on a "scorched earth policy." The infestation is not continuous and the insecticide is applied only to areas where it is known to exist. The small outlying areas are being treated first to prevent further spread and of the large generally infested areas only a portion is treated in any one year.

The method of eradication, namely, the application in granular form of two pounds of either dieldrin or heptachlor per acre is based on an analysis of research information compiled from State and Federal sources. Use experience on other control programs such as the white-fringed beetle and Japanese beetle was also taken into consideration before the final decisions were

made. All the data indicated that a program could be developed which would be safe and would present a minimum of hazard to the ecological balance in the areas to be treated.

To date approximately 130,000 acres have been treated. This includes a block of 12,000 acres at El Dorado, Arkansas, treated nearly a year ago. Reports indicate the program is successful in eradicating the ants. No active mounds have been found in the El Dorado area and the results look equally good in other locations treated to date. Observers vitally interested in the impact of this program to other forms of life have not reported serious disturbances in the area as a whole.

Close liaison has been established with the Fish and Wildlife Service to continue their observations and to keep us informed currently as to the effect this program may have on fish and wildlife in the area. Experience to date indicates that a successful program can be carried out with a minimum hazard to the beneficial forms of life present.

We believe that the points mentioned in your letter were given ample consideration before the initiation of the fire ant eradication program. We recognize of course that in any program where insecticides are used, certain precautions are necessary. Our experience has shown that insecticides can be applied successfully using very definite guidelines which can be established to minimize the hazard to fish and wildlife and to preclude any hazard to domestic animals and human health. Such guidelines are being followed in the operation of all control and eradication programs in which the U.S. Department of Agriculture participates.

In order to permit you to judge for yourself who was right, here are parts of an article on the results of the program by William L. Brown, Jr., of the Department of Entomology of Cornell University, an outstanding biologist and a world authority on ants:

With astonishing swiftness, and over the mounting protests of conservation and other groups alarmed at the prospect of another airborne 'spray' program, the first insecticides were laid down in November, 1957. The rate of application was two pounds of dieldrin or heptachlor per acre . . . Dieldrin and heptachlor are extremely toxic substances -- about 4-15 times as toxic to wildlife as is DDT. Many wildlife experts and conservationists as well as entomologists both basic and economic, felt a sense of forboding at the start of a program that would deposit poisons with 8-30 times the killing power of the common forest dosage of DDT (one pound per acre in gypsy moth control).

. . . The misgivings of the wildlife people seem to have been justified, since the kill of wildlife in sample treated areas appears to have been high in most of those that have been adequately checked. The USDA disputes many of the claims of damage, but their own statements often tend to be vague and general.

. . . Although the USDA claims that the evidence is inconclusive in some cases, there does exist contrary information indicating that stock losses from ant poisons may sometimes be significant.

. . . A serious blow was dealt the program in late 1958, when treatments were only one year old; Senator Sparkman and Congressman Boykin of Alabama asked that the fire ant campaign be suspended until the benefits and dangers could be evaluated properly. Then, in the beginning of

1960, the Food and Drug Administration of the Department of Health, Education, and Welfare lowered the tolerance for heptachlor residues on harvested crops to zero, following the discovery that heptachlor was transformed by weathering into

a persistent and highly toxic derivative, heptachlor epoxide, residues of which turn up in milk and meat when fed to stock. Some state entomologists now definitely advise farmers against the use of heptachlor on pastures or forage.

. . . The original plan set forth in 1957 called for eradication of the ant on the North American continent, by rolling back the infestation from its borders, applying eradication measures to more control foci in the main infestation, and instituting an effective program of treatment of especially dangerous sources of spread, such as nurseries. Nearly four years and perhaps 15 million dollars after the plan was announced, the fire ant is still turning up in new counties, and is being rediscovered in counties thought to have been freed of the pest in Arkansas, Louisiana, Florida, and North Carolina.

Subsequently a bait was found that allowed effective fire-ant control. It was claimed that the insecticide in the bait, Mirex (a chlorinated hydrocarbon), was virtually harmless to vertebrates and bees. Starting in 1962 Mirex was sprayed by aircraft over large areas with three applications per year. Then in 1972, when it was discovered that Mirex was killing juvenile shrimp and crabs, the Environmental Protection Agency (EPA) forbade spraying near waterways and limited applications to once a year. Subsequently Mirex was shown to be a weak carcinogen. [1] In 1976 it was agreed that all forms of Mirex were not to be used after June 1978. [1a]

In 1975 the USDA decided to give up its fire ant campaign, and Secretary of Agriculture Earl Butz blamed the EPA restrictions for the failure of the program. The EPA responded, quite correctly, that a decade of unrestricted Mirex use had failed even to contain the fire ant, let alone exterminate it. As Brown commented, "[*S. invicta*] . . . is very well-named, for it truly is unconquerable." [2]. Ecologist Edward O. Wilson of Harvard University, famous as the author of Sociobiology, [3] is also the authority on ant behavior and ecology. He responded to the USDA decision by pointing out that a program to exterminate the fire ant was questionable even if the only undesirable side effect was to kill other ants: "Ants occupy one of the middle links in the food chain -- they consume other small insects and are scavengers that recycle nutrients from decomposing material in fields and woodlands -- and no one has ever examined the long-range consequences of killing off lots of ants."

The USDA and state governments spent almost $150 million on the fire-ant fiasco, almost none of it on research that might have led to appropriate controls. The program, of course, had strong political support in the South, since the ant is an annoying pest and because a lot of federal money was spent locally in futile attempts to exterminate it. Ed Wilson wrote an appropriate epitaph for this classic boondoggle: "The fire ant control program in the South is the Vietnam of entomology."

SOME IMPORTANT PESTICIDES[4]

The left-hand column in Table A3-1 gives the commonest names for the insecticides, other names by which they are known, and the chemical designations. (Sometimes on labels a chemical designation may be simplified. For instance, aldrin will sometimes be listed simply as "hexachlorohexahydro-*endo*, *exo*-dimethanonaphthalene.) The second column gives the general uses of the chemicals, coded as follows:

Acar.	=	acaracide (used against mites)
Ins.	=	insecticide (used against insects)
Syn.	=	synergist (makes insectide more potent)
MP	=	moth-proofer
C. fum.	=	commodity or space fumigant
S. fum.	=	soil fumigant
Sys.	=	systemic insecticide (taken up by plant)
Nem.	=	nematocide (kills roundworms)

The right-hand column indicates mammalian toxicity judged by experiments on rats (no symbol), rabbits (Rb), white mice (M), or dogs (D). They are mostly given as LD50 -- that is, the dose level that killed 50 percent of the experimental animals. The doses used in studying acute toxicity are in parts per million of live animal

[4]Adapted from *Bulletin of Entomological Society of America*, 1969, vol. 15, pp. 85-135.

weight. AO = acute oral toxicity; AD = acute dermal (skin application) toxicity. Chronic oral toxicity (CO) is the highest level (parts per million in diet) at which no effect is seen in 90 days or more.

Fumigant toxicities: VA = acute vapor toxicity, the highest level in ppm thought not to be dangerous to human beings with 60 minutes exposure; VC = chronic vapor toxicity, same for 8 hours per day, 5 days per week.

For example, chlordane killed 50 percent of rats tested in different experiments at oral doses of 283-590 milligrams per kilogram (mg/kg) of body weight. When chlordane was applied to the skin, 50 percent of the rats died at doses of 580 mg/kg in at least one experiment, but in another, a dose of 1600 mg/kg did not produce 50 percent deaths. In rabbits more than 50 percent were

killed with a skin dose of 780 mg/kg. In rat experiments diets with greater than 25 or less than 150 ppm did not produce symptoms in 90 days or more.

As a general rule there will be a reasonable correlation between other mammals and human beings in the toxicity of these compounds. Thus TEPP, with an AO of 0.5-2 in rats is exceedingly toxic to people. An amount equal to about one-millionth of your body weight will kill you. DDT, on the other hand, is much safer as far as acute exposure is concerned.

Note that chlorinated hydrocarbons appear in several groups: "Chlorinated aryl hydrocarbons," "DDT relatives," and "fumigants" (paradichlorobenzene). The chemical structures of a sample of insecticides and one herbicide are shown in Figure A3-1.

TABLE A3-1 Some Important Pesticides

CHLORINATED HYDROCARBONS

ORGANOPHOSPHATE INSECTICIDES

CARBAMATE INSECTICIDES FIGURE A3-1 The chemical structures of insecticides and one herbicide. Three general classes are shown: chlorinated hydrocarbons, organophosphates, and carbamates. The herbicide 2,4-D (2,4-dichlorophenoxy acetic acid) is also a chlorinated hydrocarbon and is shown for comparison. The herbicide 2,4,5-T (2,4,5-trichlorophenoxy acetic acid) has the same structure as 2,4-D, except that it has three chlorine atoms on the phenyl ring, the additional one in the 5 position.

APPENDIX 4
Reproduction and Birth Control
REPRODUCTIVE ANATOMY AND PHYSIOLOGY

According to those who have been involved in the Planned Parenthood movement, the two greatest obstacles to successful birth control are ignorance and prudery. In fact, the two often go together. Women who have been raised to fear and dislike sex will often resist learning the facts of reproduction and be very reluctant to discuss any aspect of the subject, including birth control, with their doctors or anyone else. Regardless of such psychological problems, women who are ignorant of their own anatomy and the significance of the menstrual cycle are very likely to have failures in their birth control programs, simply because they do not understand how they work or why. Here is one more argument for good sex education programs in schools, churches, and in the home. [1] A sound understanding of the reproductive process is essential to the effective use of at least the conventional methods of birth control. There is even enough uncertainty among educated persons about human reproductive biology and contraception to make a brief review appropriate here. [2]

Conception occurs when a *spermatozoon* (sperm cell) from a man meets and fertilizes an *ovum* (egg cell) within a woman's body. The various forms of contraception are designed to prevent that occurrence in a number of ways, either by erecting a physical or chemical barrier between sperm and egg or through adjustment of the hormone system (see next section of text).

Spermatozoa are manufactured continuously by the millions daily in a man's testes. This goes on from the age of puberty (around fourteen) until very old age. Each spermatozoon contains the genetic information that the man passes on to the child in the event conception takes place. But unless it meets and fertilizes an egg cell, it dies within a few days. These microscopic, active cells, which resemble minute tadpoles, are emitted in the hundreds of millions each time a man ejaculates. The testes are also the source of production of the male hormone, *testosterone*, which is released to the bloodstream and is responsible for sexual activity and for the development of a man's secondary sexual

---

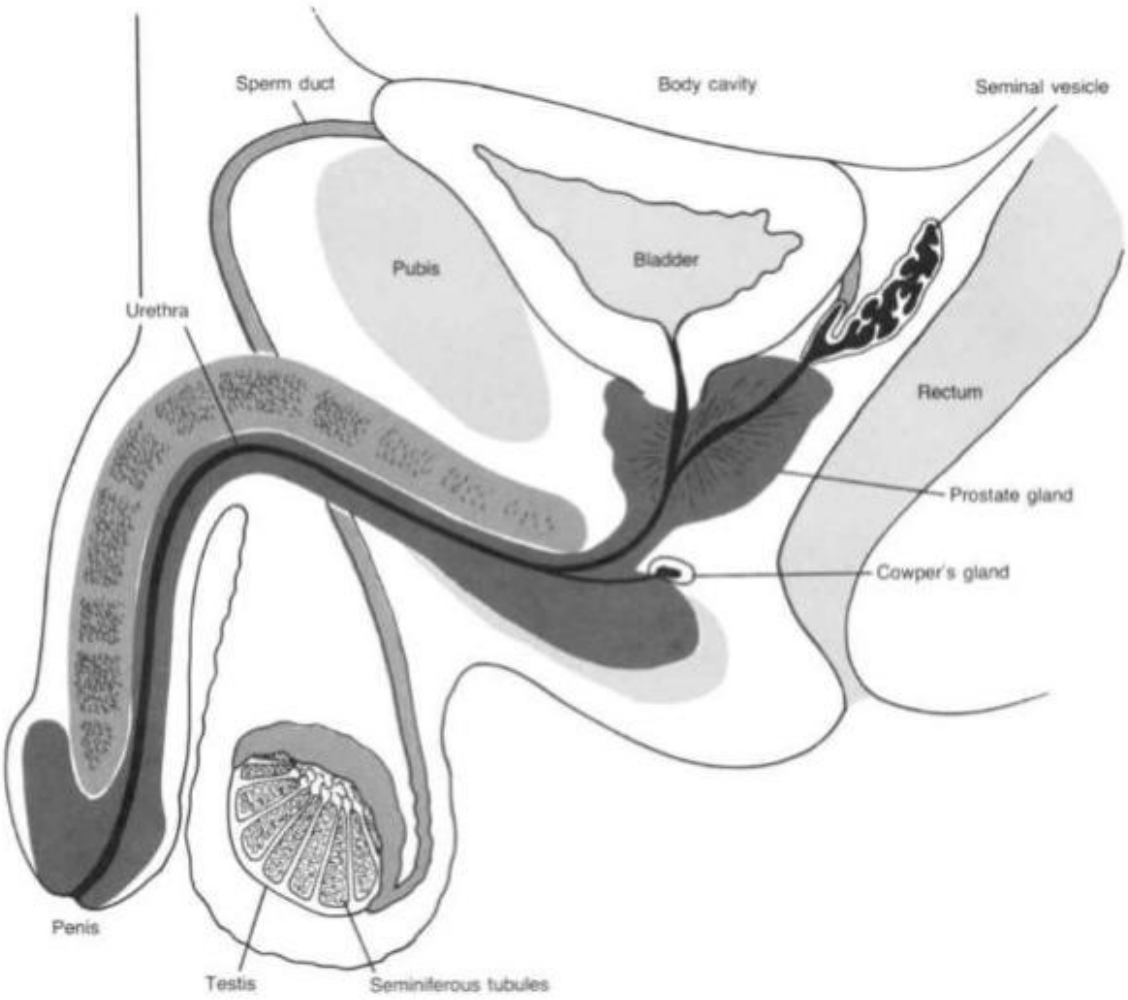

FIGURE A4-1 Male genital organs.

characteristics such as a deep voice, a beard, and typical male body structure.

When the spermatozoa are mature, they are moved upward through one of a pair of sperm ducts (*vas deferens*) to the *seminal vesicle* (Figure A4-1). This acts as a reservoir for storage until the man ejaculates. Each vas deferens opens into the urethra, a tube that extends the length of the penis. During intercourse when the man experiences his climax, or orgasm, a series of muscular contractions force the sperm cells in a fluid matrix known as semen through the urethra, injecting it into the vagina. The semen is a mixture produced in several glands including the prostate. It provides the spermatozoa with protection after they are deposited in the vagina, which is a relatively hostile environment.

The woman's reproductive cells (ova) are present in immature form in her ovaries from birth (Figure A4-2). From puberty (around 13) until she reaches menopause, somewhere around the age of 45 or 50, one egg cell or ovum (or occasionally two or more, which may result in multiple births, usually twins or triplets) is brought to maturity approximately every 28 days. A single ovum is so small it would be visible to the naked eye only as a tiny speck, yet it is many thousands of times larger than a spermatozoan. Besides the mother's genetic contribution to the

potential child, the egg cell contains nourishment to support the early development of the embryo, should the ovum be fertilized.

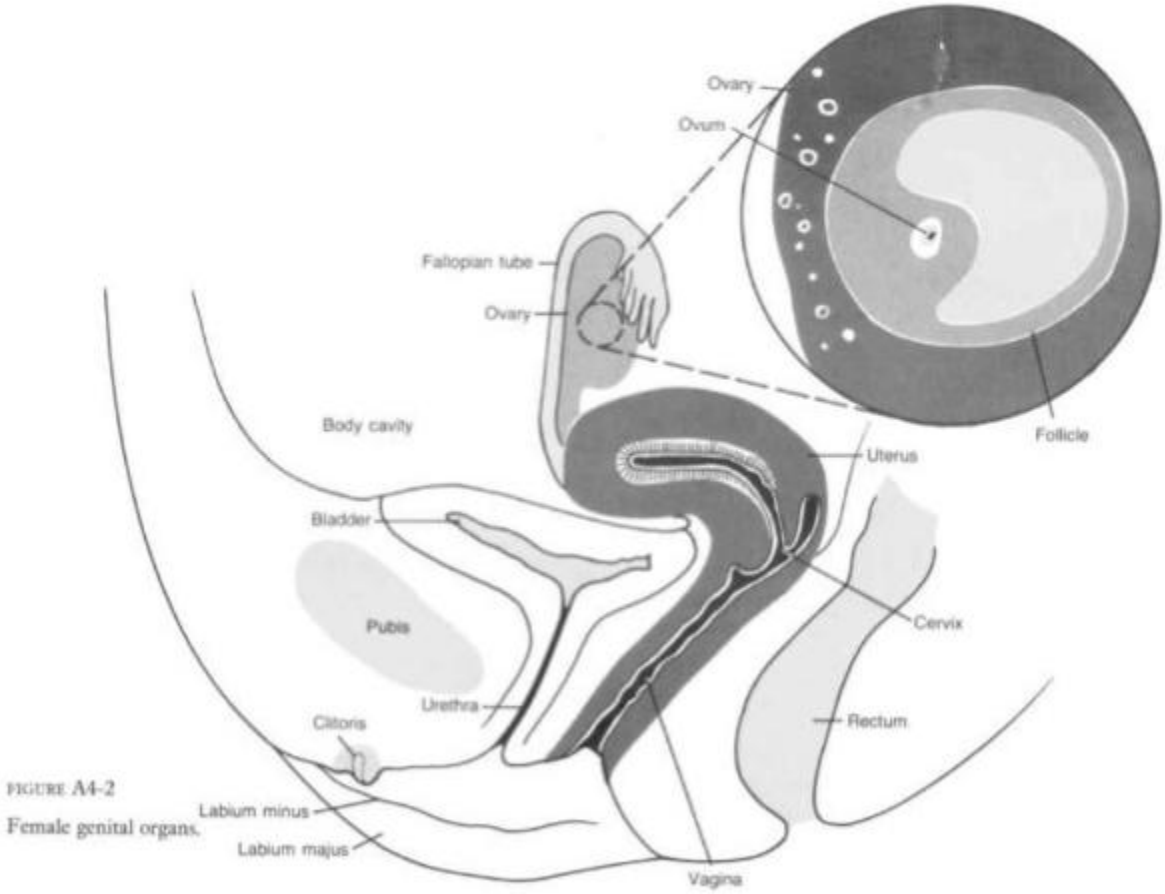

FIGURE A4-2
Female genital organs.

Besides being the source of ova, the ovaries also secrete the female hormones, which, along with certain pituitary hormones, regulate the woman's menstrual cycle and the successful completion of a pregnancy. *Estrogen*, which is also responsible for the secondary sexual characteristics of a woman, such as the developed breasts and the pelvic bone structure adapted to the bearing of children, initiates the maturation of the ovum and the preparation of the uterus for pregnancy. In one of the two ovaries each month, an ovum, which is surrounded by a group of cells called a follicle, ripens and is released (ovulation). It enters the adjacent flared end of a trumpet-shaped structure known as a fallopian tube and travels slowly down it toward the uterus (womb). If fertilization does not take place during the one or two days of this journey, the ovum begins to deteriorate and eventually dissolves.

After the ovum is discharged from the follicle, the latter develops into a structure called a *corpus luteum*, which begins to secrete the other female hormones, including *progesterone*.

Progesterone further stimulates the buildup of a lining of cells and extra blood vessels in the uterus, in preparation to receive a developing embryo for implantation. If conception (fertilization) does not occur, the corpus luteum degenerates and ceases to produce progesterone. In the absence of fertilization, about 14 days after ovulation the lining of the uterus is sloughed away through the vagina over a period of 5 or 6 days in the process of menstruation. Then the cycle begins again.

Spermatozoa that have been deposited in the vagina during coitus still have a long way to go relative to their size and vulnerability before fertilization can take place. The mucus lining of the vagina is acid, and the sperm cells cannot live long in such an environment. They must find their way into and through the thick mucus filling

the cervical canal of the uterus. They are equipped with an enzyme capable of dissolving the mucus, but apparently it requires large numbers of them to dissolve enough to allow them to reach the uterus. Many, of course, are lost along the way. The uterus provides a favorable, alkaline environment, but the spermatozoa must still find their way from there into the fallopian tubes. If an ovum is descending one of the fallopian tubes as the remaining several thousand spermatozoa swim up it, one of the spermatozoa may succeed in penetrating the capsule of the egg cell. Once one has penetrated, the fertilized ovum is impervious to all the others. The ovum continues to descend the tube, undergoing cell division as it goes. When it reaches the uterus and is implanted in the uterus wall, it is a rapidly developing embryo. At this early stage it is already producing a hormone, a gonadotropin that stimulates the corpus luteum to continue producing progesterone, thus preventing menstruation.

Within five weeks, the growing embryo has established its *placenta*, the organ through which food and oxygen from the mother and wastes and carbon dioxide from the fetus (as it is called after the third month) are exchanged. Throughout the rest of the pregnancy the placenta also secretes progesterone, which protects the implantation of the fetus and suppresses ovulation and menstruation. Nine months from conception, the infant is born. With powerful contractions from the uterus, the child is forced through the cervix and vagina, which expand to accommodate it. During lactation (the period when the mother is producing milk) menstruation usually continues to be suppressed, although ovulation may or may not occur.

METHODS OF BERTH CONTROL

For individuals or couples who wish to avoid having children, either temporarily or permanently, a wide variety of methods exist from which to choose. Since one person's ideal contraceptive may be completely unsuitable for one reason or another for someone else, it is prudent to be familiar with all the possibilities and with the advantages and disadvantages of each.

Conventional Methods

Among the so-called conventional methods and devices for birth control are the condom, the diaphragm, and the cervical cap; various creams, jellies, and foams; the douche; and the rhythm

system. All of these are intended to prevent the meeting of sperm and ovum. More recent additions to the arsenal include the contraceptive pill and the intrauterine device (IUD). Some of these methods and devices are more effective than others, and each has advantages and disadvantages that may make it more or less suitable for a couple at a particular stage of life. Beyond these contraceptives, for a couple whose family is complete, there is sterilization. When contraceptives fail, as they occasionally do, the unwanted pregnancy may be ended by abortion.

In addition to the conventional methods of birth control, there are certain folk methods, used mainly in the United States by ingenious teenagers, including douches with soft drinks and condoms devised from plastic wrapping materials. Despite the ingenuity they reflect, they cannot be recommended--especially the douche. Their effectiveness is unknown, although that of the plastic condom may be quite high.

New methods of birth control are now being developed and tested in laboratories, and some of them may become available to the public within the next few years.

The condom. Many men have learned about the condom in the armed forces, where it is presented to them as a means of avoiding veneral disease. It is also one of the most popular and most effective means of birth control. Usually made of rubber, the condom is a very thin sheath that fits tightly over the penis during intercourse and retains the semen after ejaculation. Its advantages lie in its simplicity of use and its availability. The failure rate is low, especially if the man has been instructed in its proper use. Care is especially required to insure against spillage of semen at the time of withdrawal. Defective condoms are seldom encountered and can be guarded against by inspection before use. Unlike other devices, condoms require no fitting or prescription by a doctor; but many men complain that they interfere with the enjoyment of intercourse by reducing sensation

and by causing an interruption of foreplay in order to apply them.

The diaphragm. This device, essentially a rubber cup with a rubberclad rim of flexible spring steel, is designed to fit over the cervix, where it acts as a barrier to sperm. It is inserted into the vagina before intercourse, and is left in place for several hours afterward. Before insertion it is coated on the edges and underside with a spermicidal jelly or cream to prevent any sperm from getting through underneath. A well-fitted, properly used diaphragm is a highly effective contraceptive, [3] but it is relatively complicated to use compared to the condom and some other methods. To ensure a proper fit, it must be prescribed by a doctor, who also instructs the woman about its placement and use. When in position, it cannot be felt, and its use does not in any way interfere with either partner's enjoyment of sexual relations.

The cervical cap. Like the diaphragm, the cervical cap bars entrance of sperm into the uterus. It is made of plastic or metal, fits tightly over the cervix, and may be left in place for long periods of time. It need be removed only for menstruation. If properly fitted, the cap is extremely effective. Its main disadvantage lies in the difficulty of placing it correctly.

Spermicidal agents. A variety of spermicidal jellies and creams are available that can be deposited in the upper vagina with special applicators. Although these agents are less effective than the devices discussed above, they have the advantage of being easier to use than mechanical contrivances, and they require neither fitting nor prescription by a doctor.

Foam tablets, aerosols, and suppositories are similar to the jellies and creams, and operate on the same principles. The foam varieties may be more effective than the others, perhaps because they are more thoroughly dispersed in the vagina.

Rhythm. Also referred to as periodic abstention, rhythm is the only method of birth control now sanctioned by the Roman Catholic church. The basic idea is to abstain from sexual relations during the several days each month when a woman might be capable of conceiving. The difficulty is that this period is often hard to determine, particularly in women with irregular menstrual cycles. To avoid conception, the couple must abstain from coitus for at least two days before and one-half day after ovulation. Unfortunately the occurrence of ovulation can only be determined after the event, and not too accurately even then. When ovulation has taken place, the woman's temperature rises about half a degree and drops again when her menstrual period begins. The time of ovulation must be predicted on the basis of carefully kept records of her previous menstrual and temperature cycles. To allow an adequate safety margin, several additional days should be included both before and after the estimated fertile period. Thus, the period of abstention amounts to a considerable fraction of the month, to the inevitable detriment of the conjugal relationship, especially since the fertile period usually is a time when the woman is relatively more receptive to sexual relations. What is worse, the rhythm method is one of the least effective of birthcontrol methods. Approximately one woman in six has a cycle so irregular that the system will not work at all for her. But the church claims this is the only natural form of birth control, since it requires no mechanical devices or chemical solutions--a claim that neglects the necessary preoccupation with calendars, clocks, thermometers, pencils, and graphs.

The pill. The modern steroid oral contraceptive, generally known as "the pill," is the most effective means of birth control generally available today, except for sterilization and abortion. When taken without fail according to instructions, it is virtually 100 percent effective.

The pill is composed of the female hormone estrogen and of progestin, a synthetic substance that is chemically similar to the natural progesterone produced by a woman's ovaries. This combination is believed to act by suppressing ovulation. The pill is taken daily for 20 or 21 days of the 28-day cycle, beginning on the fifth day after the onset of the menstrual period. The steroids may be administered sequentially or in a combined form. In the sequential system, the estrogen is

---

[3]Judith Wortman, "The diaphragm and other intravaginal barriers--a review". *Population Reports*, series H, no. 4, January 1976.

administered alone during the early part of the cycle, with the progestin added only during the latter part. The pills have the effect of regularizing the menstrual cycle to exactly 28 days, even

in women who have never had regular cycles before. Moreover, menstrual flow is noticeably reduced, or even occasionally suppressed altogether. Most women consider these effects advantageous.

As is inevitable with any drug, particularly a hormonal drug, there may be undesirable side effects. Most of these, however, wear off within a few months or can be dealt with by adjusting the dosage or changing brands. Many of them resemble the symptoms of pregnancy, which in a sense is hormonally simulated in the woman's body by the progestin. The most common side-effects are tenderness and swelling of the breasts, weight gain and retention of fluid, nausea, headaches, depression, nervousness and irritability, changes in complexion, and bleeding. About one in four or five women taking the pill experiences one or more of these symptoms.

The advantages of an oral contraceptive are obvious, even apart from the advantage offered by its effectiveness. Its use is far removed in time from the act of intercourse, and there are no mechanical devices or chemicals except the pill to deal with. On the other hand, the woman must remember to take it each day, which requires a fairly high degree of motivation. The chances of pregnancy increase with each forgotten pill.

Apart from the relatively common minor side effects of the pill, there is a small risk of more serious consequences. Research published in the United Kingdom in 1968 revealed that women over the age of 35 who were using the pill had a significantly higher chance (8 per 200,000) of dying of thrombophlebitis (inflammation of veins together with blood clots) or pulmonary embolism (blood clots in the blood vessels of the lungs) than women of the same age who were not using the pill (1 in 200,000). The risk is less than one-half as high in either case for women under 35. Up to the age of 40 the risk of death from thromboembolic disease while using the pill is considerably less than that of death resulting from pregnancy. Demographer Charles Westoff has calculated that the risk of death from complications of pregnancy and childbirth to a population of women who switched from the pill to other, less effective forms of birth control, would be about three and a half times as great as the risk of death from thromboembolism incurred from using the pill. [4] The estrogen component of the pill appears to be responsible for development of the thromboembolic disorders. Subsequent research in both the United Kingdom and the United States has generally supported these findings [5] and also discovered that women on the pill have a similarly higher risk of suffering strokes or developing gall bladder disease. Less serious but more common is the increased incidence of bladder infection (20 to 30 percent higher) among pill takers. In 1975 another British study was published indicating that women over 40 who take the pill have about 5 times as great a probability of having heart attacks as nonusers. [6]

Because of the thromboembolic and stroke risks, the United States Food and Drug Administration (FDA) for several years has required that the labels of the Pills warn of possible hazard to women with histories of venous disorders, high blood pressure, and cardiac problems and has strongly recommended that doctors prescribe only low-estrogen pills. Since 1976, prescribing instructions have been required to warn that they are unacceptable for women over 40. [7]

Newer versions of the pill contain far lower doses of steroids--one-tenth as much or less as early versions on which most research on side effects is based. These low-dose pills appear to cause a somewhat lower incidence of thrombosis and other dangerous side effects, although how much cannot be determined until they have been in use for a decade or two.

On the plus side, it has long been known that the pill acts to regularize and moderate menstrual periods. The result of this is a considerable reduction in irondeficiency anemia, a circumstance potentially of considerable benefit to women in LDCS, where anemia

[7]FDA planning to rewrite "pill" label, *Intercom* (Population Reference Bureau), vol. 3, no. 11 (December 1975).

is very common among women of child-bearing age. Association of the pill with breast cancer remains inconclusive. A British study indicated that the pill may reduce the incidence of abnormalities in the breasts and thus may act to prevent breast cancer. [8] But a California study in 1975 suggested that women who use the pill before child-bearing may run a higher risk of having breast cancer later in life. [9] And a small study in Colorado indicated that the sequential pill--in which the two steroids are taken in sequence rather than simultaneously--may increase the risk of uterine cancer. [10]

While these dangerous side effects are alarming, it must be remembered that the risks are of very low level, indeed. Even for women over 40, the risk of heart attack is about 55 per 100,000. Moreover, heart attack has usually occurred where other predisposing factors, such as heavy smoking, high blood pressure, obesity, or a family history of heart disease, also were present. For younger women the risks of heart attack or other hazards are far smaller. [10a]

With the possible exception of aspirin (which also has potentially dangerous side effects), no other drug has been taken by tens of millions of people regularly over extended periods of time. This phenomenon both increases the likelihood that such side effects will show up and makes it possible for them to be detected at such statistically low levels. But much more time will have to pass and much more data will have to be gathered before definite statements can be made about long-term risks associated with the use of oral contraceptives. Society is in somewhat the same position in regard to the pill as it was when DDT first came into use. The risks must be weighed against the benefits, and the long-term risks are still unknown. From what we know now, it appears that for most women the benefits still outweigh the risks; the latter can be minimized through close supervision by an alert physician. Obviously, continued monitoring of the long-term effects of the pill (or any other hormonal contraceptives) is essential.

Despite the frequency of minor side effects and the low, but genuine risk of very serious ones, the pill is currently the most popular modern method of contraception around the world. Over 50 million women are using it, some 9 million in the United States alone.

The IUD. The intrauterine device, or IUD, as it is generally known, is a plastic or metal object that is placed inside the uterus and left there for as long as contraception is desired. It comes in a variety of shapes, each having advantages and disadvantages relative to the others. The most commonly used today include the Lippes loop, the ring, and the Dalkon shield (Figure A4-3), although new styles are continually being developed.

That the presence of a foreign body in the uterus would act to prevent pregnancy has been known for a long time, but until modern antibiotics and sterilization techniques were available, they were unsafe to use. Exactly how these devices work is uncertain, but the likeliest possibility is that they prevent the implantation of the fertilized egg after conception. Recent research indicates that in human beings IUDs prevent implantation by changing the condition of the endometrium (lining of the uterus), making the interior of the uterus in various ways inhospitable both to the fertilized egg and to spermatozoa.

The newest IUDs are models made of or incorporating active substances that directly prevent pregnancy. Two of these, the Cu7 and the Copper T, are made of copper. A third version contains progesterone in minute amounts, which acts locally essentially as the pill does in inhibiting ovulation. [11]

The advantages of an IUD for the user are several: the primary one is that once in place it can be forgotten (except for the copper and hormone-releasing versions, which must be replaced after a couple of years). There are no pills to remember, no contraceptive materials to deal with. This is a great advantage for an individual whose lack of motivation, educational background, or financial resources would make other forms of birth

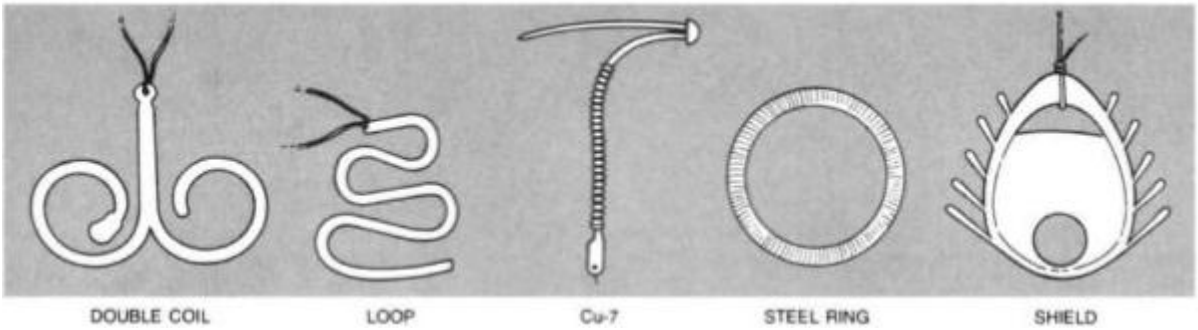

FIGURE A4-3
Various forms of IUDS.

control unreliable or too expensive. The device costs only a few cents. It must be inserted and subsequently checked at least once, perhaps a month later, by a physician or a paramedical person. These advantages have made IUDs especially popular with family-planning programs in less developed nations, where about half of the 15 million IUDs currently in use are being worn.

About 10 percent of women spontaneously expel the device, sometimes without knowing that they have. This tendency varies greatly with age and also with the number of children previously borne. Young women with no children are most likely to expel it; women over 35 with several children are least likely. Expulsion is most likely to occur during the first year of use, and becomes less and less likely thereafter.

For the woman who can successfully retain the IUD, it is a highly effective contraceptive, exceeded only by the pill and sterilization. The pregnancy rate varies somewhat with size and type of IUD and is higher among young women (as it is under any conditions). The risk of pregnancy drops considerably after the first year of use and continues to drop for succeeding years.

Many women have to remove the IUD because of such side effects as bleeding and pain. Some bleeding and discomfort are usual for a short time after insertion, and an increased menstrual flow is common; but when these symptoms continue or are excessive, it is best to remove the IUD. Such problems usually disappear immediately after the device is taken out. There is no evidence that IUDs lead to the development of cancer. The IUD may rarely be associated with pelvic inflammation, though there is some question whether the device is primarily responsible or only aggravates a preexisting condition. In very rare cases perforation of the uterus occurs, and there is considerable evidence that this happens during insertion. Even given these rare but dangerous side effects, the death rate for IUD users is quite low: 1 to 10 per 1 million woman years of use in the United States.

In 1974 the Dalkon shield was discovered to be associated with severe infections in pregnancy, which led to several deaths. The distribution of the device was suspended for six months while investigation proceeded. It appeared that the construction of the tail (which normally protrudes from the uterus) caused it to act as a "wick" for bacteria to invade the uterus, which can be especially dangerous if the wearer is pregnant. The FDA allowed the shield to be distributed again in the United States under a careful program of medical supervision and reporting, but the

Agency for International Development (AID) and Planned Parenthood have suspended its use, at least until the "wick" problem is solved.

Most differences in performance among IUDs probably are smaller than differences in the quality of care from one clinic to another. When the IUD is fitted by well-trained and experienced people, and reassurance and support are given to patients who experience side effects, failure rates are generally lower, regardless of the type of device used. In general, the IUD is probably most suitable for women over 30 who have had at least one or two children; they are least likely to have a birthcontrol failure, to have problems with side effects, or to expel the IUD.

TABLE A4-1
Twelve-Month Failure Rates of Contraceptive Methods (pregnancies per 100 woman years of use)

Method	Among couples intending to delay their next pregnancy	Among couples intending to prevent further pregnancies
Pill	7	4
IUD	15	5
Condom	21	10
Diaphragm	25	17
Foam	36	22
Rhythm	38	21
Douche	47	40
Overall rates all methods	26	14

Effectiveness of methods. Table A4-1 gives information on the effectiveness of various methods of birth control. Effectiveness is calculated on the basis of 100 woman years--that is, the number of women per 100 women using a given method who become pregnant in a one-year period. Among 100 women using no contraception, 80 can expect to be pregnant by the end of one year. The failure rates are based on actual results from the United States 1970 National Fertility Survey. No distinction is made between failure of the method itself or carelessness in its use. The results make it clear, however, that a stronger motivation for preventing further pregnancy (rather than spacing or delaying births) results in a lower failure rate even with such effective methods as the pill or the IUD.

Sterilization. For couples whose families are complete and who wish to rid themselves of concern about contraceptives, sterilization is often the best solution. This procedure can be performed on either partner, but it is much simpler for the male. A vasectomy takes only fifteen

or twenty minutes in a doctor's office. The procedure consists of cutting and tying off the vas deferens, thus making it impossible for sperm to be included in the ejaculate (although the absence of the sperm may only be detected by microscopic examination).

The female's operation until recently has been much more complicated, involving an internal surgical operation with the usual attendant risks. The abdomen was opened under anesthesia and a section of the fallopian tubes cut and removed so that the ova could not pass through. This operation was usually done right after the birth of a baby, a time when the tubes are in a relatively accessible position. A new method, involving an approach through the vagina is now being used by some doctors and may prove to be simpler and safer. Perhaps even better than the vaginal approach is the new "minilaparotomy," which has been tested in several countries including the United States, Thailand, and the Philippines. This method involves a tiny incision--only about an inch long--and can be done with only local anesthetic. Because the procedure is simpler and the recovery time so much shorter, the minilaparotomy can be done on an outpatient basis. Needless to say, this also reduces the costs to the patient. [12]

Contary to the beliefs of many people, sterilization does not in any sense end one's sex life. Vasectomy is *not* castration. The hormonal system is left intact, and sperm are still manufactured by the body; they are just prevented from leaving it. Sexual performance, including orgasm and ejaculation, is normally unchanged. Complications are rare; when they occur, they usually are minor and temporary. [13] In the few cases in which psychological problems develop, they usually are found to have grown out of previously existing disturbances. In many cases, psychological improvement is reported as worry over unwanted children ends.

The same is generally true for the female; her hormones still circulate, ova are still brought to maturity and released, the menstrual cycle goes on. All that is changed is that her ova never reach the uterus, nor can sperm travel up the fallopian tubes. Complications from the newer, simplified procedures appear to be infrequent, although they can be relatively serious. Adverse psychological reactions to sterilization among women are extremely rare.

---

[12]Female sterilization by mini-laparotomy, *Population Reports*, series C, no. 5 (November 1974); for a review of all current tubal sterilization methods, see Judith Wortman, "Tubal Sterilization: Review of methods", *Population Reports*, series C, no. 7 (May, 1976).

[13]"Vasectomy: What are the problems?" *Population Reports*, series D, no. 2 (January 1975).

Some individuals hesitate to take so final a step as sterilization. Although in actual practice only a very small percentage of sterilized people ever ask to have the operation reversed, many want some assurance beforehand that it can be done. For men, successful reversal of the operation is achieved in less than 30 percent of cases on the average. New methods of sterilization, notably one in which plastic plugs are inserted into the vas deferens, show promise of being virtually 100 percent reversible, but this alternative is not yet available. [14] The woman's operation can be reversed in 25 to 66 percent of the cases, but women have been even less likely than men to request restoration of fertility.

For men who still have lingering doubts about taking the final step of sterilization, it is now possible to preserve a sample of sperm in a frozen sperm bank for up to ten years. In the future this period can probably be extended. Thus, if a second wife years later wishes children, they can be provided by artificial insemination. Another possibility is that live sperm might be removed from the father's testes and used for insemination, although this has not yet been attempted, as far as we know.

Abortion. Abortion is the arrest of a pregnancy. The medically approved method of inducing abortion in the early stages today is through a fairly simple procedure known as vacuum aspiration, which removes and destroys the embryo. This procedure can be done any time during the first twelve weeks of pregnancy on an outpatient basis; over 85 percent of abortions in the United States are now done this way. After the thirteenth week, an abortion becomes considerably more complicated and hazardous, the usual method being saline injection.

Until around 1970, abortion was illegal in the United States and most other countries of the world. Since then, laws have been changed in a growing number of countries. Illegal abortion is extremely dangerous, whereas legal abortion, practiced in appropriate medical circumstances in the early months of pregnancy, is safer than pregnancy and childbirth. The legal changes and moral issues surrounding abortion are discussed in Chapter 13.

Possibilities for the Future

Many possible ways of interfering with the reproductive process have yet to be explored; some of the most promising of these are under investigation in laboratories or are being tested clinically in human beings. Within the next decade or two a variety of new methods of birth control should become available for general use. Some of the methods currently being developed show considerable promise as practical approaches for population control in less developed countries, where the simplest and cheapest methods are most useful in family-planning programs. Most of the new contraceptives are designed for women; some are extensions of the research that produced the Pill. [14a]

Progestins Among the developments most likely to prove useful soon are various forms of low, continuous dosages of the steroid progestin. Like the higher dosage of progestin combined with estrogen in the present pill, the low progestin dosages also suppress ovulation. This method seems to be slightly less effective than the combined-hormone pill, but the use of progestin alone has the advantage of avoiding some of the more dangerous aspects of the pill, such as the increased risks of thromboembolism, heart attack, and stroke that seem to be associated with the estrogen component. But some side effects do appear. Some women have complained of headaches and dizziness. A more serious drawback seems to be a tendency toward irregular bleeding and amenorrhea (absence of menstruation).

Very large study programs involving thousands of women around the world have been carried out with two forms of low-dose progestins: a minipill, taken daily with no "time off" to keep track of; and intramuscular injections at three-month or six-month intervals. The minipill by 1975 was being used by several hundred thousand

[14]Lois E. Bradshaw, "Vasectomy reversibility: A status report", *Population Reports*, series D, no. 3 (May 1976). More recently, a method using microsurgery has proven relatively successful in cases in which reversal was attempted within 10 years after the vasectomy: *Family Planning Perspectives*, Microsurgery is promising for vasectomy reversals, vol. 8, no. 5 (Sept /Oct 1976), p. 246.

[14a]Recent research on contraceptive technology and reproduction is reported in R. V. Short and D. T. Baird, "A discussion on contraceptives of the future", *Proceedings of the Royal Society of London, B. Biological Sciences*, vol. 195, pp. 1-224, 10 December 1976.

women around the world. For the most part, it is used by women who are lactating (which is disrupted by estrogen) or who for other reasons should avoid the estrogen component of the combined pill. [15]

The three-month injections of progestins are now in use in clinical studies by the International Planned Parenthood Federation in over fifty countries around the world, including the United States. This method of birth control appears to be particularly useful as a postpartum contraceptive to provide spacing between children, as it does not interfere with lactation. Several LDCS, particularly Egypt, are interested in the method for this reason.

Both the minipill and injections produce the side effects of irregular bleeding and amenorrhea, which is disturbing to some women, although the bleeding usually disappears after a few months. These side effects may be controlled by administering very small doses of estrogen for a few days each month. Potentially more serious, the effect of the injections may not be immediately reversed after the injections are stopped.

Another way of administering progestin is the "time capsule," which can be implanted under the skin by a hypodermic needle. The material of which the capsule is made--a silicone rubber known as Silastic or a lactate polymer--releases the steroid at a constant rate over a long period of time, potentially 25 or 30 years. Its effect is completely reversible by removal. Time capsules for shorter periods (a year or less) are now being clinically tested and should be generally available within a few years if they prove successful.

Another version of the continuous low-dosage progestin is the vaginal ring. This device fits over the cervix like a diaphragm, but, rather than blocking the entrance, it slowly releases progestin into the surrounding tissues. It needs replacement only once a month.

Progestin administered in low dosages in any of the ways discussed above shares with the progestin--estrogen pill the advantages of relatively high effectiveness and convenience and has the additional advantages of being far less complicated to use (especially the implanted capsule) and of avoiding the hazards of estrogen. It is quite likely that all these forms will be considerably less expensive, at least by the time they can be used in large quantities. If long-term testing does not turn up some new and unanticipated difficulty, progestin holds considerable promise as an effective mode of birth control.

The morning-after pill. Morning-after birth control usually consists in taking a substantial oral dose of an estrogen (in the United States, most often it is diethylstilbestrol, or DES) within a few days after coitus. [16] Pregnancy is prevented, but the woman usually feels quite sick for a day or two. In early 1975, the Food and Drug Administration authorized the use of DES as a postcoital contraceptive by the general public, despite considerable evidence that it may cause cancer. Many young women whose mothers a generation ago took DES to prevent threatened miscarriages have developed cancer of the vagina or the cervix. DES is known to be carcinogenic in other circumstances as well.

In view of this link with cancer and the discomfort associated with its use, we certainly do not recommend the DES morning-after pills. Other hormonal compounds are also being investigated, but they may present similar or other hazards. A far better--and safer--move is to obtain an early abortion. In the earliest weeks, this is a very simple procedure, sometimes euphemistically called "period extraction." The best of all choices, of course, is to use effective contraceptives.

Prostaglandins. A few years ago the discovery of prostaglandins, a group of hormonelike substances related to fatty acids and found in many mammalian tissues, sparked hope that a new abortifacient agent might be developed. Prostaglandins are now being used successfully in some second-trimester abortions, and newer, still-experimental methods are expected to reduce sideeffects and shorten the period between induction and abortion (now up to forty-eight hours). Unfortunately, research results for the early weeks of pregnancy so far have been disappointing, however, largely because of side effects and incomplete abortion. Newer ways of using prostaglandins combined with other drugs in early pregnancy may avoid these problems. [17]

---

[15]Minipill: A limited alternative for certain women, Ward Rinehart, *Population Reports*, series A, no. 3 (September 1975).

[16]Ward Rinehart, "Postcoital contraception: An appraisal", *Population Reports*, series J, no. 9 (January 1976).

[17]Ronald Shalita, "Prostaglandins promise more effective fertility control", *Population Reports*, series G, no. 6 (September 1975).

Methods for men. Attempts to find steroid or other chemical forms of contraceptives for men have until recently been remarkably unsuccessful. Usually they are aimed at reducing or interfering with spermatogenesis. Several of the early compounds proved to be incompatible with the consumption of alcoholic drinks, a serious drawback in many societies. When progestins were administered to volunteers, spermatogenesis was suppressed, but so was the production of the male sex hormone testosterone, which led to impotence and a loss of libido. These effects might be avoided by adding the male hormone androgen to the progestins, but such a mixture has been thought likely to cause side effects as the pills for women do.

An Australian research team in late 1974 announced the results of a successful early test on an estrogenandrogen combination that had for fifteen years been used as a treatment for osteoporosis and for symptoms of "male menopause" without the appearance of serious side effects. The only side effect found was mild nausea in some patients at the beginning of the

treatment. The only disadvantages were that the drug took effect slowly --from 12 to 18 weeks-- and wore off slowly (up to 9 months) after discontinuation. [18]

Another new possibility, so far tested only in mice, is the use of a compound known as 5-thio-D-glucose, which appears to prevent spermatogenesis by interfering with the testes' sugar metabolism. This method capitalizes on the fact that only the testes (and some tumors) depend on a particular sugar, D-glucose, for energy. Administering 5-thio-D-glucose to mice induces a mild diabeteslike condition (which may reduce appetite and thus be useful in weight control) and atrophy of the testes. The latter effect appears to be completely reversible within eight weeks in mice with no effect on subsequent offspring for two generations. [19]

In addition to these promising chemical approaches to male contraception, two removable mechanical devices still in the experimental stage are being developed as means of reversible sterilization. One, invented by an Indian physician, consists of a clip that can be attached to the vas deferens. The other is a plastic or silicone plug that can be inserted in the vas deferens. Not only could these new devices be used as temporary contraceptives but they also would satisfy the objections to sterilization from those who fear taking an irreversible step. Unfortunately, sometimes the vas remains permanently closed if the clip is removed after a long period of time. The plugs sometimes have the opposite drawback. The vas may expand so that sperm can pass through, or the plug may eventually deteriorate. The technique shows promise, however, and the plugs are being tested in human volunteers by the Association for Voluntary Sterilization.

Other new methods. A variety of chemicals are being tested on laboratory animals, in the hope of finding some that will not have the drawbacks of the steroid compounds. But since many seem to act by influencing some part of the natural hormone system, it is not too surprising that similar side effects have been associated with some of them. Nevertheless, these possibilities, which have only begun to be investigated, deserve careful examination.

At least one folk method of contraception is being looked into. A South American weed, Stevia rebaudiana, has traditionally been used by the Indians in Paraguay as a contraceptive. Each day the women drink a cup of water in which the powdered weed has been boiled. Experiments with rats indicated a reduction in fertility of from 57 to 79 percent compared with a control group, with low fertility lasting up to two months after withdrawal of the drug. Undoubtedly many such folk methods are known in various human cultures. Some of them may be quite effective and might prove adaptable to the urgent need for population control, particularly in less developed countries.

Some other ideas being tested in laboratories are more sophisticated versions of contraceptives already in use. These include long-lasting spermicidal creams, removable blocks for the fallopian tubes, [20] and a version of the vaginal ring that releases a spermicide. There are also experiments on immunizing a woman against her husband's sperm and others on enzymes or chemicals that decapacitate sperm. Whereas many of these ideas may

---

[18]Hormone mixture makes a male pill, *New Scientist*, December 19, 1974, p. 860.

[19]T, H. Marigh, "5-Thio-D-Glucose. A unique male contraceptive", *Science*, vol. 186, p. 431 (

November 1, 1974).

[20]Reversible sterilization by fallopian blocking, *New, Scientist*, March 28, 1974, p. 800.

prove impractical for one reason or another, others may ultimately be developed into useful additions to the contraceptive arsenal.

Research on male contraceptives is also proceeding along some lines parallel with that for contraceptives for women. Immunizing men against their own sperm would theoretically be a way to halt sperm production. However, this possibility will require many years to develop, if it is even feasible. Another idea is to give men a hormone implant that would suppress sperm production over a period of time.

Despite these interesting lines of research, it appears that the present emphasis on contraceptives for the female will continue for some time, since research on male methods is so far behind in development.

Research and development. In the light of the current world-population situation, it is clear that research on means of birth control has been neglected for too long. Although some potentially valuable possibilities for birth control have come out of recent research, obviously we are still many years away from having an ideal contraceptive--one that is cheap, easy to use, effective, and free from unpleasant or dangerous side effects. In the United States, a *minimum* of 8 to 10 years of testing is required by law before a new contraceptive agent can be released to the general public. [21] Since contraceptive chemicals, unlike most other drugs, are intended for continuous or regular use over long periods of time, perhaps decades, by large numbers of people, the need for exhaustive testing is genuine. But there is no question that it requires a great deal of time and increasing quantities of money. Unless some incentives, including government support, are soon established to encourage research and development in the birth-control field, new contraceptive agents may be delayed in their appearance on the market even beyond the middle 1980s. In view of the world's great need for cheap, simple, and effective means of birth control, the United States and other DCs have an obligation to make positive efforts to encourage their development.

[21]See Carl Djerassi, "Birth control after 1985", *Science*, vol. 169, pp. 941-951, Sept 4, 1970, for a detailed discussion of the problems of contraceptive research and development. Since Djerassi's paper was published, disappointingly little has been done to encourage expansion of this area of research: M. A. Koblinsky, F. S. Jaffe, and R. O. Greep, "Funding for reproductive research: The status and the needs", *Family Planning Perspectives*, vol. 8, no. 5 (Sept /Oct 1976), pp. 212-224. The Ford Foundation seems to have reached similar conclusions, as reported by B. J. Culliton, "Birth control: Report argues new leads are neglected", *Science*, vol. 194, pp. 921-922, November 26, 1976.

Acknowledgments

In attempting to deal with a topic as broad and pervasive as the population-resource-environment situation, it was inevitable that we would often cover topics outside our fields of competence. Study of the literature can only partially correct for this; critiques by knowledgeable reviewers are also essential. We, of course, remain indebted to all who helped with the two editions of *Population, Resources, Environment*, for that book served as a starting point for this one. A large number of busy people have been kind enough to read all, or substantial sections of the Ecoscience manuscript. These people are listed below with brief indications of their fields of expertise when this is not clear from their institutional affiliations.

Bruce Ames, Department of Biochemistry, University of California at Berkeley (carcinogenesis); D. L. Bilderback, Department of History, Fresno State University; L. C. Birch, School of Biological Sciences, University of Sydney (ecology); Robert van den Bosch, College of Natural Resources, Division of Biological Control, University of California at Berkeley (ecology of agroecosystems, integrated control); Earl Cook, Dean of Geological Sciences, Texas A & M University (energy and mineral resources); Dana Dalrymple, Foreign Economic Service, U.S. Department of Agriculture, Washington, D.C.; Erik P. Eckholm, Senior Researcher, Worldwatch Institute, Washington, D.C. (agriculture and ecology); Gail Finsterbusch, Cabin John, Md. (agriculture); Cynthia Green, Zero Population Growth, Washington, D.C.; Denis Hayes, Worldwatch Institute, Washington, D.C. (science policy); Donald Kennedy, Department of Biological Sciences, Stanford University (neurophysiology, pesticides, science policy); Nathan Keyfitz, School of Public Health, Harvard University (demography); James Krier, School of Law, University of California at Los Angeles (environmental law, law and economics); Harold Mooney, Department of Biological Sciences, Stanford University (community ecology); Richard Norgaard, Department of Agricultural Economics, University of California at Berkeley; Robert E. Ricklefs, Department of Biology, University of Pennsylvania (population biology); Robert Risebrough, Bodega Marine Laboratory, University of California at Berkeley (ecology, pesticides); Jonathan Roughgarden, Department of Biological Sciences, Stanford University (population biology); Stephen Schneider, Deputy Head, Climate Project, National Center for Atmospheric Research, Boulder, Colo.; Kirk Smith, Environmental Health Sciences, University of

California at Berkeley (energy and health); Alan Sweezy, Division of Humanities and Social Sciences, California Institute of Technology (economics, demography); John H. Thomas, Department of Biological Sciences, Stanford University (population control, theology).

In addition, the following faculty with experience in using *Population, Resources, Environment* as a text have reviewed the entire manuscript and made many helpful comments: George Lawrence, Department of Life Sciences, Bakersfield College; Larry O. Spreer, Department of Chemistry, University of the Pacific; Matthew Tuohey, Department of Sociology, Azusa Pacific College. We have also benefited greatly from the hundreds of cards and letters commenting on *Population, Resources, Environment* sent to W. H. Freeman and Company by others using the book.

In any enterprise of this scale, one inevitably asks and receives numerous favors of colleagues and friends -- the loan of a photograph or document, a bit of technical information, or simply some advice. From others we have shamelessly pirated ideas. We appreciated all of these numerous "assists" and would like specifically to thank: Hannes Alfvén, University of California at San Diego and Royal Institute of Technocracy, Stockholm; Katie Armitage, University of Kansas; C. K. Birdsall, Department of Electrical Engineering, University of California at Berkeley; Justin Blackwelder, Environmental Fund, Washington, D.C.; David Brower, Friends of the Earth, San Francisco; Harrison Brown, California Institute of Technology, Division of Geological Sciences; Lester Brown, Worldwatch Institute, Washington, D.C.; Reid Bryson, Department of Meteorology, University of Wisconsin; Robert Budnitz, Lawrence Berkeley Laboratory; Herman Daly, Economics Department, Louisiana State University; Chester B. Dugdale, Department of Biological Sciences, Fairleigh Dickinson University; Marcus Feldman, Department of Biological Sciences, Stanford University; Dan Ford, Union of Concerned Scientists; T. K. Loy Bilderback and Don Kennedy have both gone far beyond the normal role of reviewers, having been closely involved with both editions of *Population, ResourcesEnvironment*,

Environment as well as with *Ecoscience*. Their ideas have influenced us greatly and (along with bits of their prose) have often slipped into the work uncredited. Their assistance has been extraordinary. The help of our good friend and attorney, Johnson C. Montgomery, was sorely missed after his death in December 1974. Much of the material on legal matters still bears the stamp of his thinking --

especially his pioneering work on the legal aspects of population control.

Peggy Craig, Claire Shoens, and other staff members of the Falconer Biology Library at Stanford have once more been of enormous assistance to us. Their highly competent and cheerfully given help has time and again permitted us to solve difficult bibliographic problems. Reuben Pennant has patiently Xeroxed reference materials and several drafts of manuscript. Thanks for invaluable reference work are also due Mari Wilson, librarian for the Energy and Resources Information Center at the University of California at Berkeley.

Typing chores for this edition have been handled expertly by Darryl Wheye at Stanford and Sue Black, Linda Elliott, Linda Marczak, George Moon, Becky New, Debbie Tyber, and Denise Wior at Berkeley. Seemingly endless proofreading of galleys was accomplished with the able assistance of Robert Wise and Kim Binette (in Hawaii), and Susan Mann, Glenn Lunde, Jennifer Montgomery, and Julia Kennedy (all of Palo Alto and Stanford). We are especially grateful to Julie, who devoted many hours of spare time for six weeks to the job. Julie, Jenny, and Glenn also helped in assembling the chapter bibliographies. Jane Lawson Bavelas at Stanford once again helped us with myriad aspects of the work.

Judith Quinn, our project editor, has done a superb job of polishing the manuscript, dealing cheerfully with the numerous crises inevitable in the final stages of a project of this scale. Her skill and patience have made our task much easier. The reader doubtless will appreciate the skill and attention to detail that Jean McIntosh devoted to the indices, as we appreciated her good humor in the face of preposterous time pressures.

Finally we would like to express our deep appreciation to Cheri Holdren, who put up with many "social" evenings that were long working sessions on the manuscript of this book. She cheerfully gave us aid and comfort while continuing to balance with great success the needs of her children and the initial stages of her own career as a research biologist. We hope now that the book is in hand she will think the effort worth it.

 PAGENUMBER1052

Abbreviations and Acronyms

ABM	antiballistic missile
ACDA	Arms Control and Disarmament Agency. (U.S.)
ACLU	American Civil Liberties Union
AEC	Atomic Energy Commission (U.S.)
AID	Agency for International Development (U.S.)
AMA	American Medical Association
APS	American Physical Society
ATP	adenosine triphosphate
bbl	barrel
BHC	benzene hexachloride
BHP	biological hazard potential
BOD	biochemical oxygen demand
Btu	British thermal unit
FDA	Food and Drug Administration (U.S.)
FEA	Federal Energy Administration (U.S.)
FOE	Friends of the Earth
FPC	Federal Power Commission (U.S.)
FPC	fish protein concentrate
FWPCA	Federal Water Pollution Control Administration (U.S.)
g	gram
GNP	gross national product
GPP	gross primary production
HCB	hexachlorobenzene
HEW	Department of Health, Education and Welfare (U.S.)
HTGR	high temperature gas reactor
HUD	Department of Housing and Urban

BWR	boiling water reactor
bwu	blue whale unit
C	Celsius
CAB	Civil Aeronautics Board (U.S.)
Cal	calorie
CBW	chemical & biological warfare
CEP	circular error probability
CEQ	Council on Environmental Quality (U.S.)
CIA	Central Intelligence Agency (U.S.)
CIAT	International Center for Tropical Agriculture
CIMMYT	International Maize and Wheat Improvement Center
cm	centimeter
CWP	coal workers' pneumoconiosis
D	deuterium
DC	developed country
DDD	dichloro-diphenyl-dichloroethane
DDE	dichloro-diphenyl-dichloroethylene
DDT	dichloro-diphenyl-trichloroethane
DOD	Department of Defence (U.S.)
DOI	Department of Interior (U.S.)
DOT	Department of Transportation (U.S.)
ECCS	emergency core cooling system
EDF	Environmental Defense Fund
EEC	European Economic Community
EIS	environmental impact statement
EPA	Environmental Protection Agency (U.S.)
ERDA	Energy Research and Development Administration (U.S.)
F	Fahrenheit
FAO	United Nations Food and Agriculture Organization
FCC	Federal Communication Commission (U.S.)
	Development (U.S.)
HWR	heavy water reactor
HYV	high yielding varieties
IAEA	International Atomic Energy Agency
ICRP	International Commission on Radiological Protection
IEA	International Energy Agency
IFAD	International Fund for Agricultural Development
IITA	International Institute for Tropical Agriculture
ILO	International Labor Organization
IMCO	Intergovernmental Maritime Consultative Organization
INCAP	Institute for Nutrition for Central America and Panama
IPPF	International Planned Parenthood Federation
IR	infrared
IRI	instantaneous rate of increase
IRRI	International Rice Research Institute
IUD	intrauterine device
IWC	International Whaling Commission
J	joule
JCAE	Joint Committee on Atomic Energy (U.S. Congress)
K	Kelvin
K	carrying capacity
kcal	kilocalorie
kg	kilogram
kj	kilojoule
km	kilometer
kW	kilowatt
kW	kilowatt-hour
l	liter
